

**Towards Total Neutrino Mass
Constraints through
Multi-Wavelength Gravitational
Lensing Measurements**

Hironao Miyatake
Nagoya University

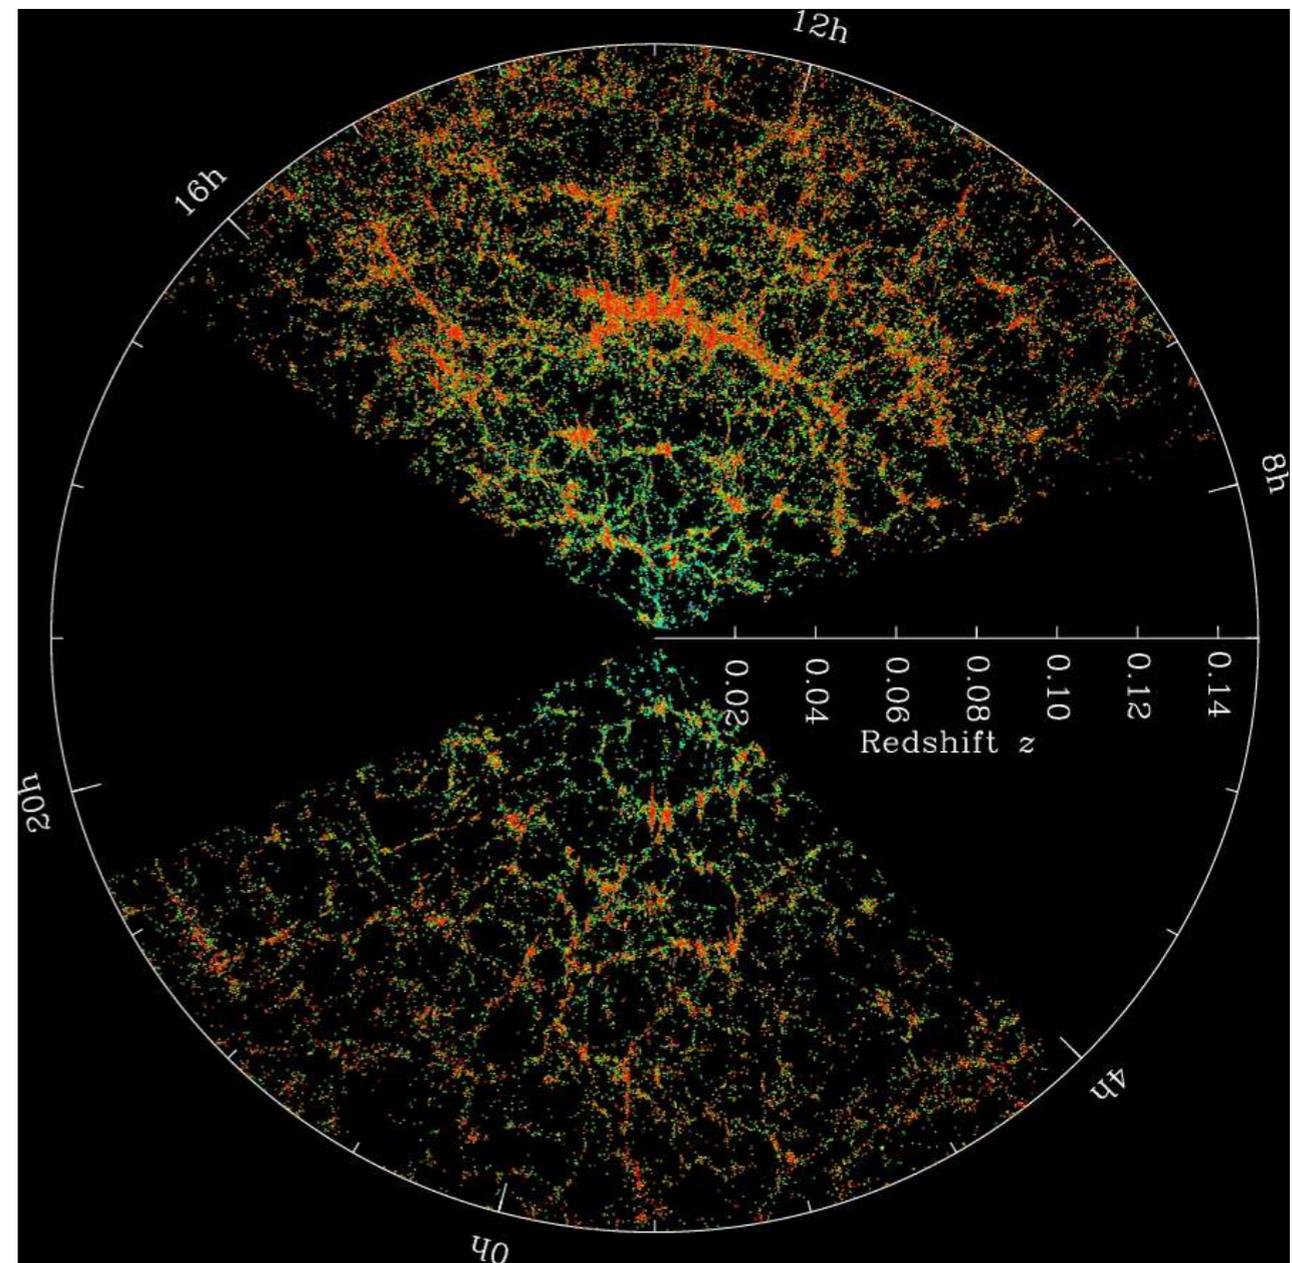

Outline

- Large scale structure of the Universe
- Neutrinos in large scale structure
- Galaxy cluster number count
- Gravitational lensing as a cluster mass estimator
- Pushing the maximum redshift by combining Subaru Hyper Suprime-Cam (HSC) and CMB experiments

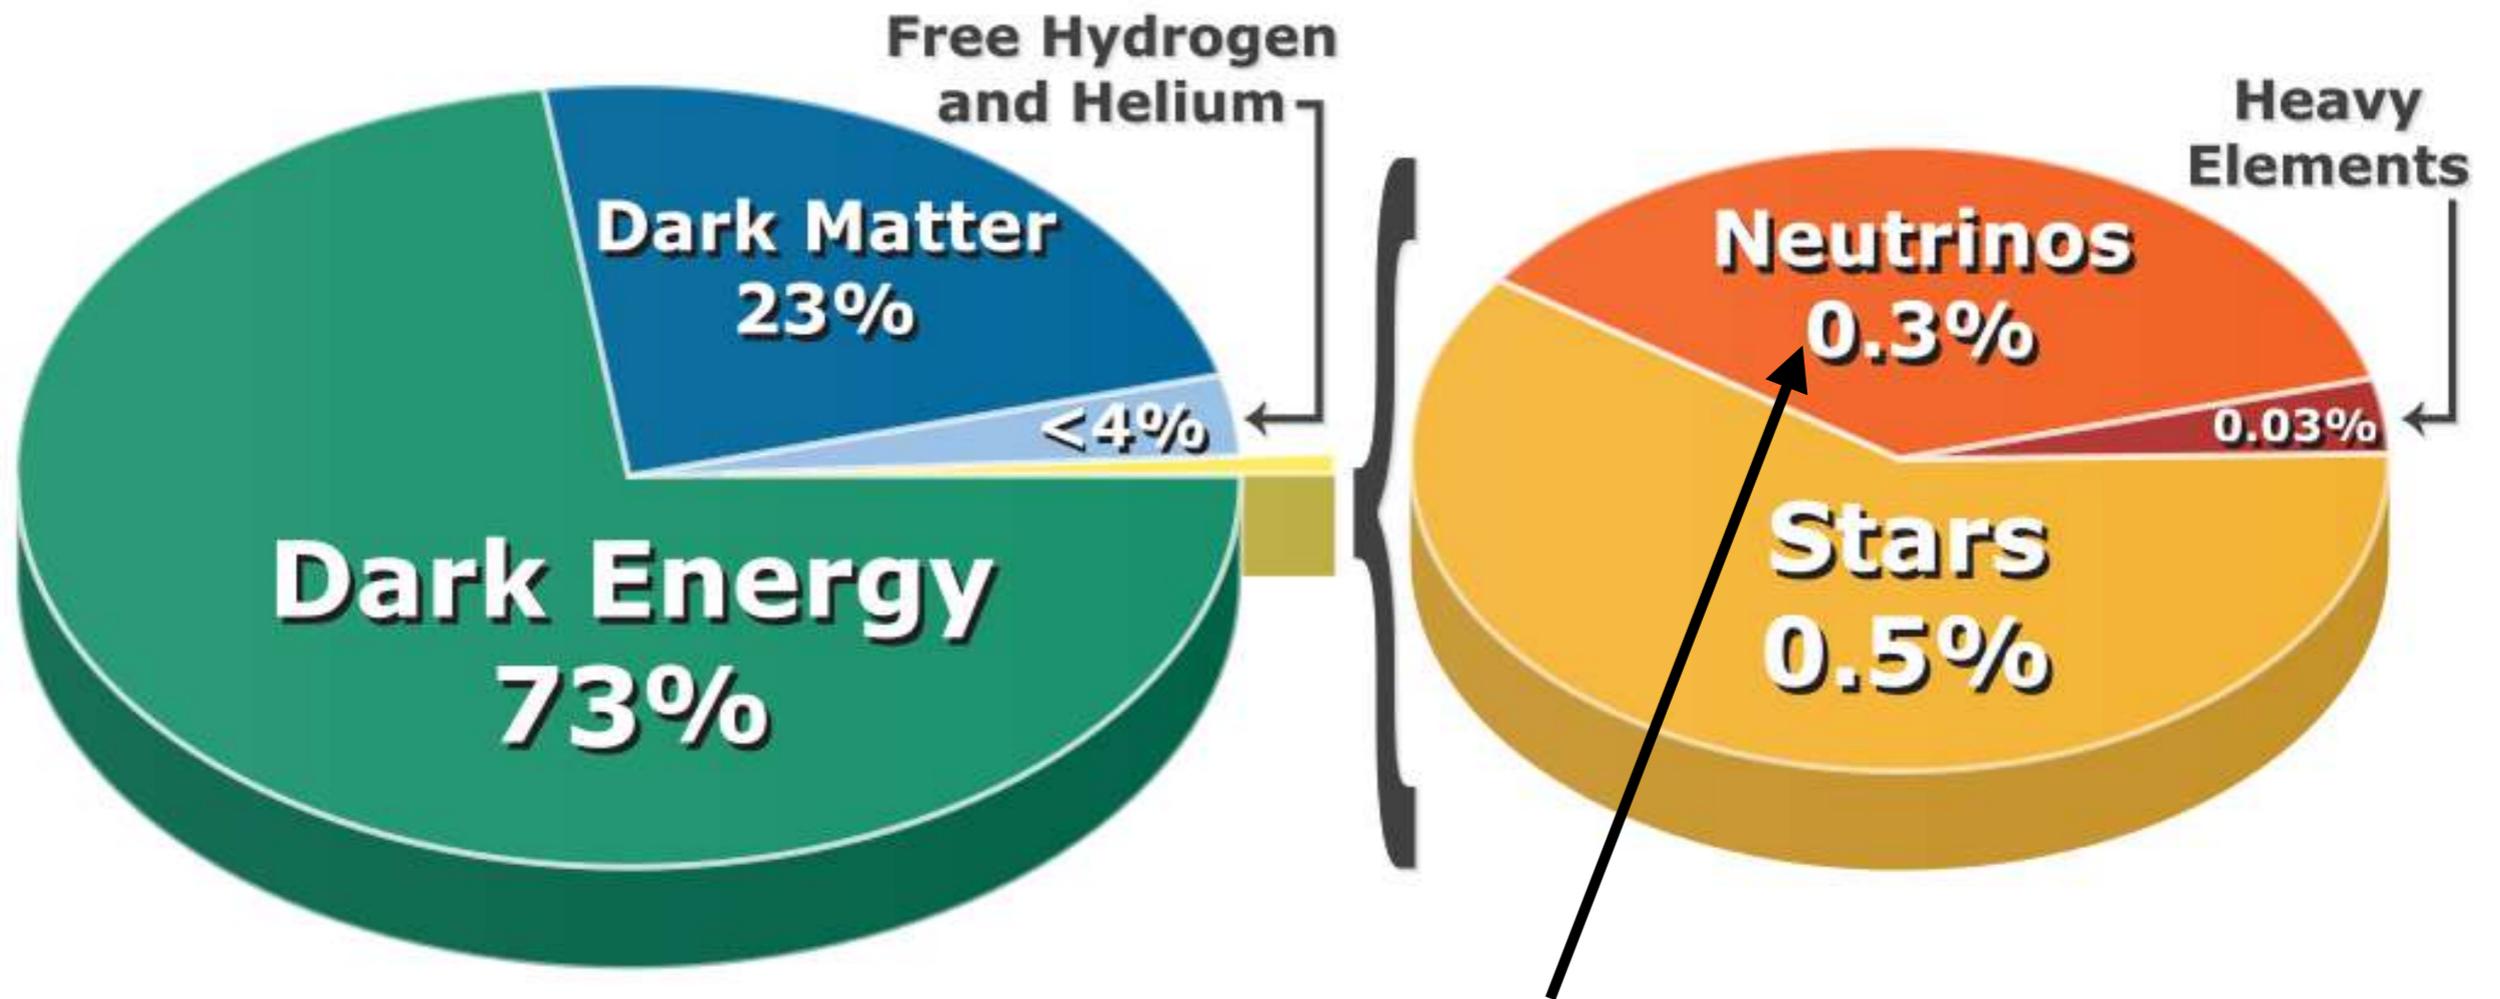

Large Scale Structure (LSS)

- LSS of the universe was formed from small scales (stars) to large scales (galaxies and galaxy clusters).
- Time evolution of LSS tells us what the universe consists of, e.g., dark matter and dark energy, and their natures.
- Since we do not know the initial condition of the universe, we need to rely on **summary statistics**, e.g., cluster number counts and matter power spectrum.

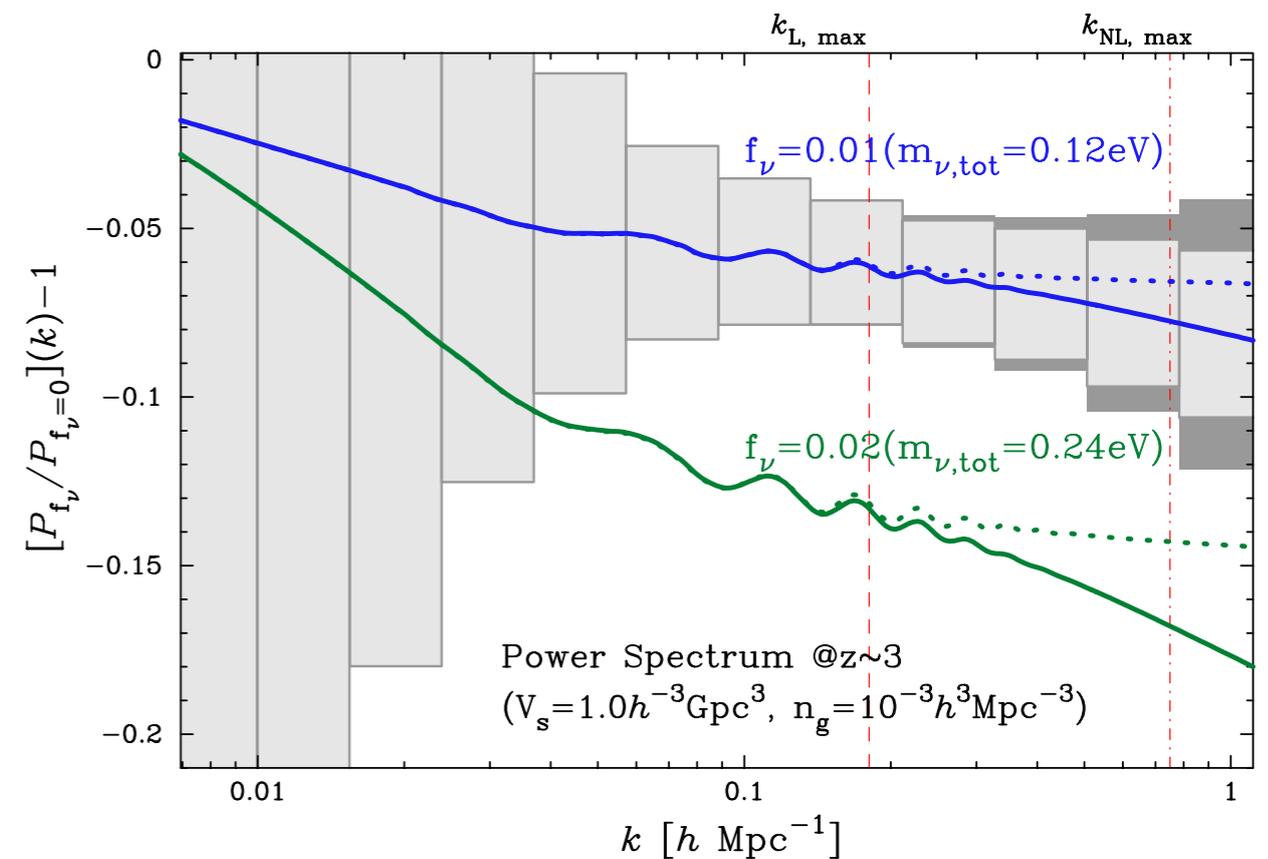

Neutrinos matter!

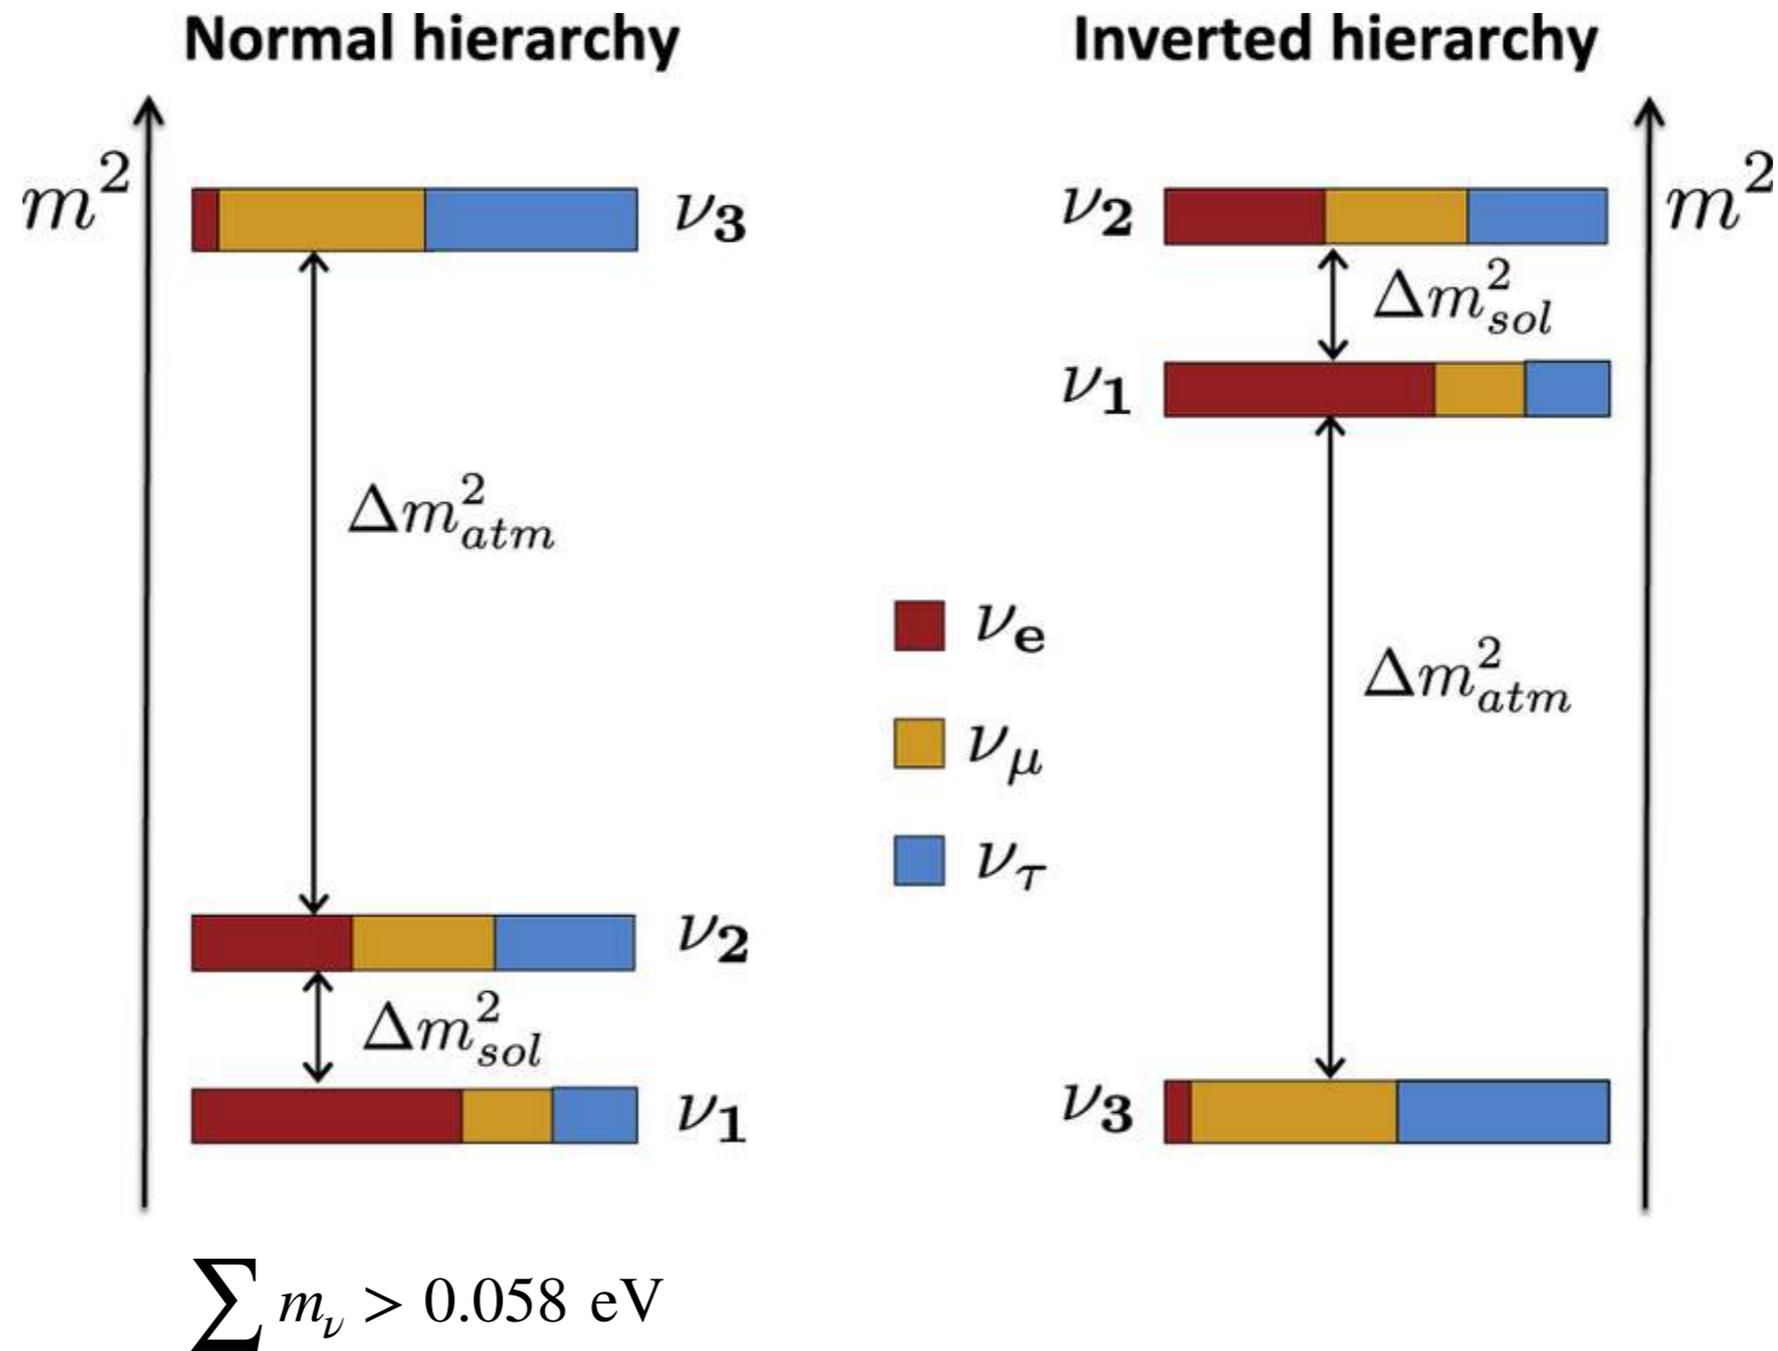

Upper Limit!

Neutrinos in LSS

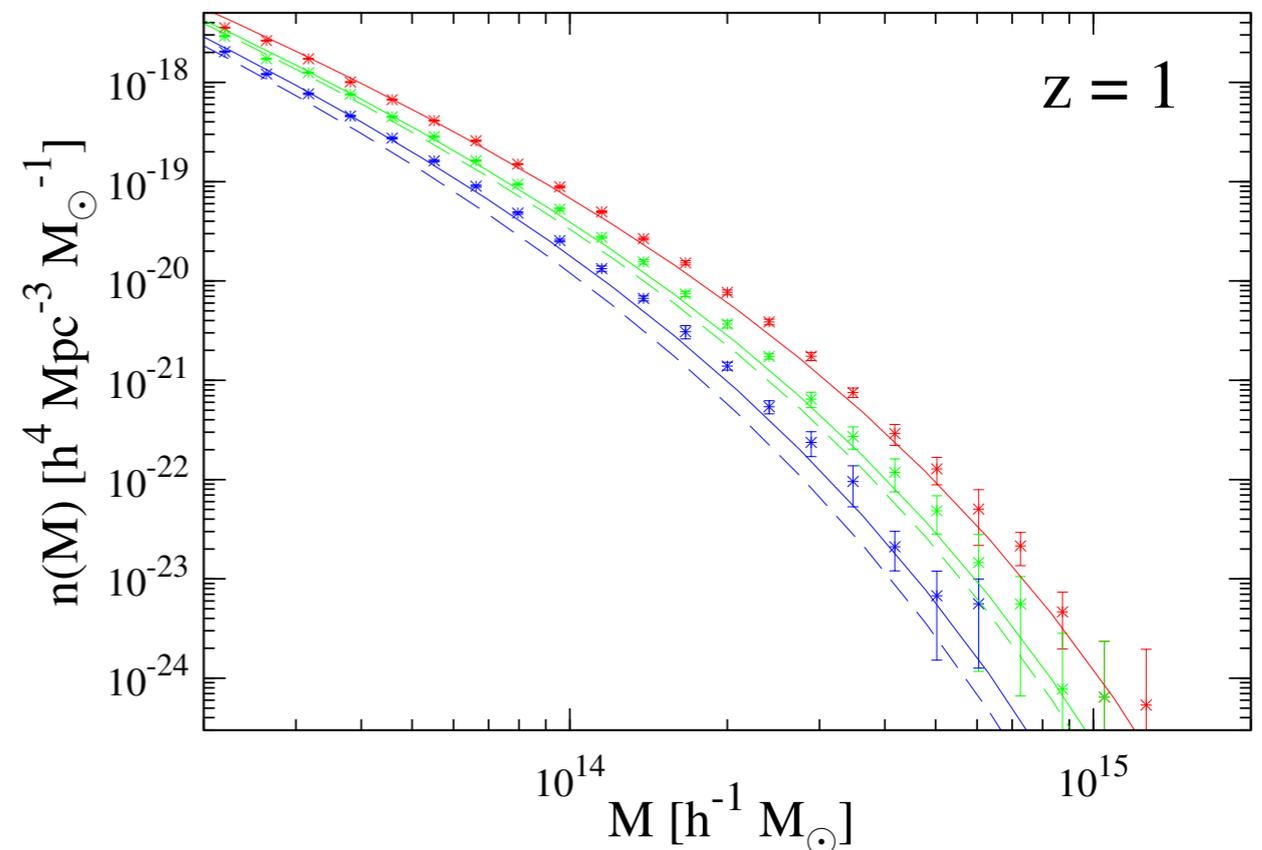

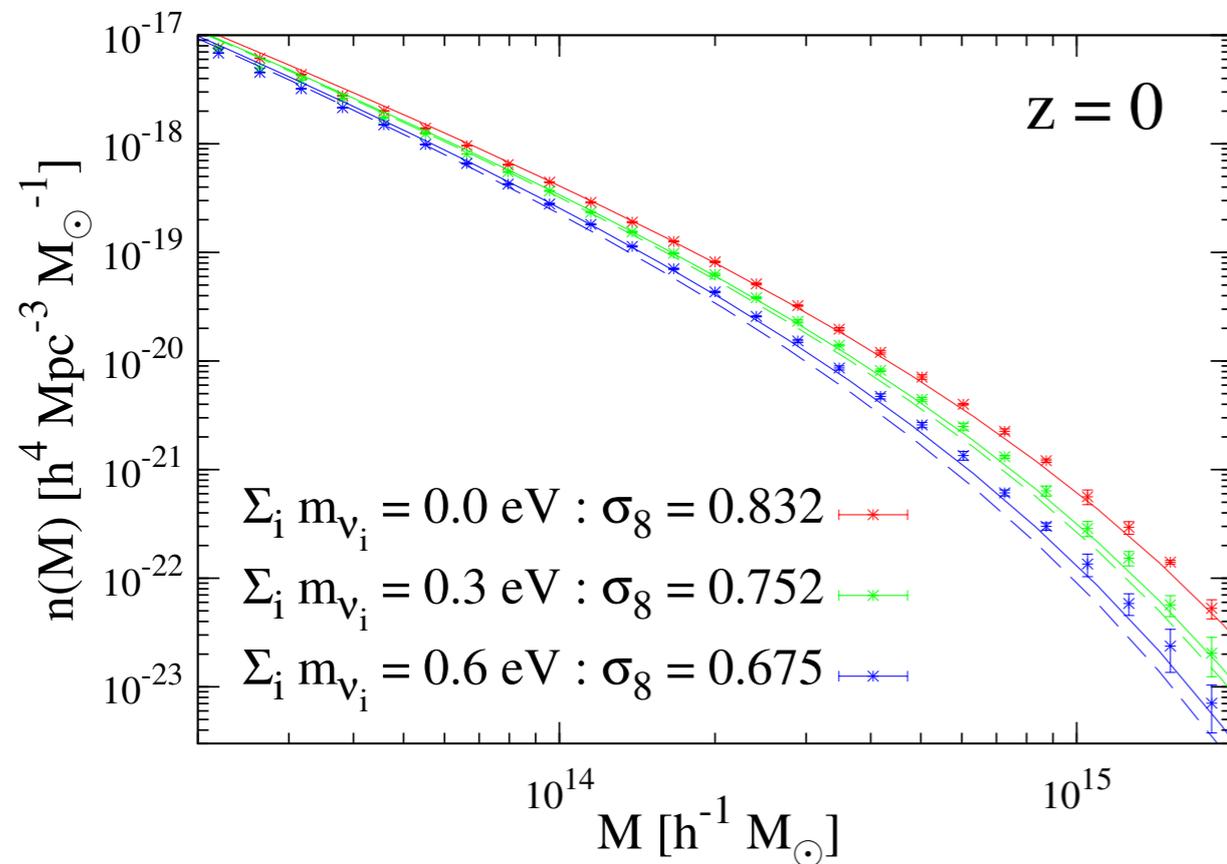

- Due to the large free streaming, massive neutrinos do not **cluster** at small scales, but do at large scales.
- **Small scale structures are suppressed** by massive neutrinos.
- We can place an upper limit on **total neutrino mass** through large scale structure measurements.

Neutrino Mass Hierarchy

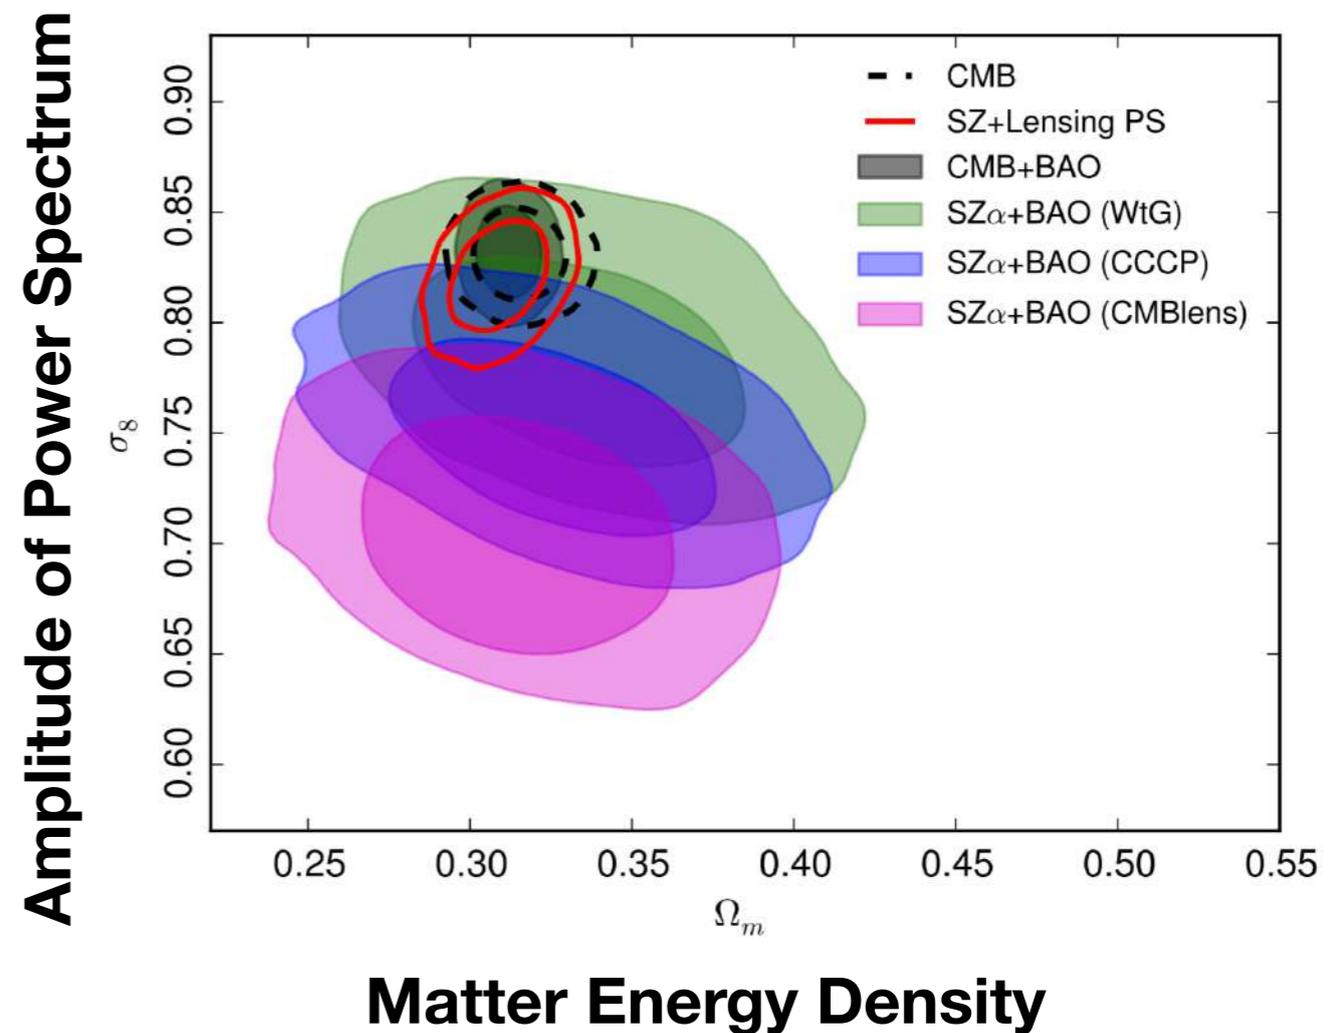

Cluster Number Count

- Cluster number count is one of the powerful probes of LSS.
- Neutrinos suppress cluster formation and changes cluster evolution.

Cluster Mass Calibration

- The number of galaxy clusters detected by Planck is smaller than the prediction from the primary CMB measurement.
- Estimating cluster mass is tricky, e.g., from X-ray and SZ observables, one needs to assume hydrostatic equilibrium.
- Cluster mass should be calibrated **before talking about anything about neutrinos!**

Mass Calibration by Weak Lensing

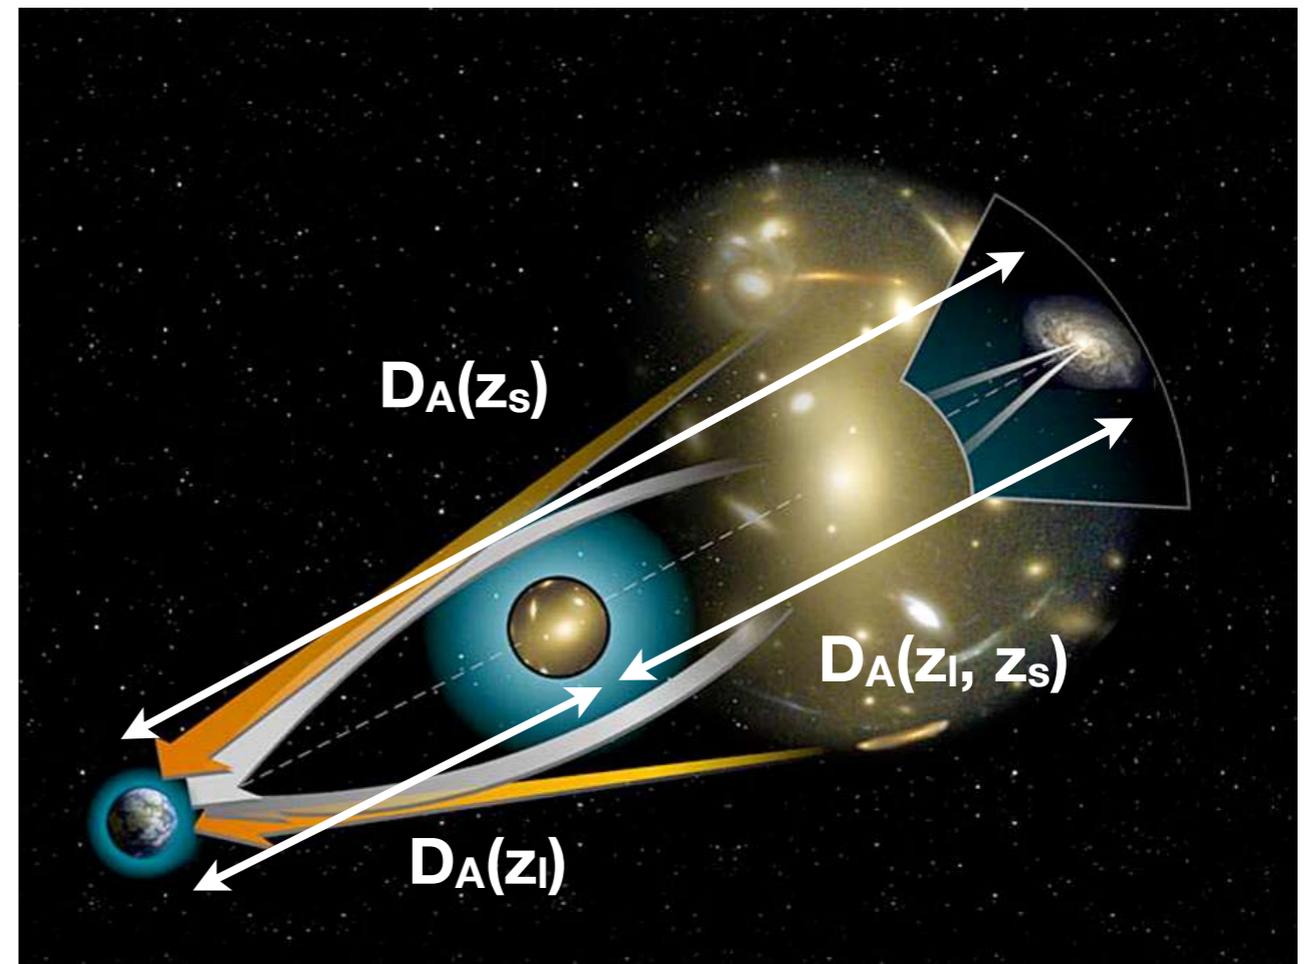

lensing shear

$$\gamma \propto \frac{D_A(z_l, z_s) D_A(z_l)}{D_A(z_s)} \delta(z_l)$$

lensing efficiency

matter (lens)

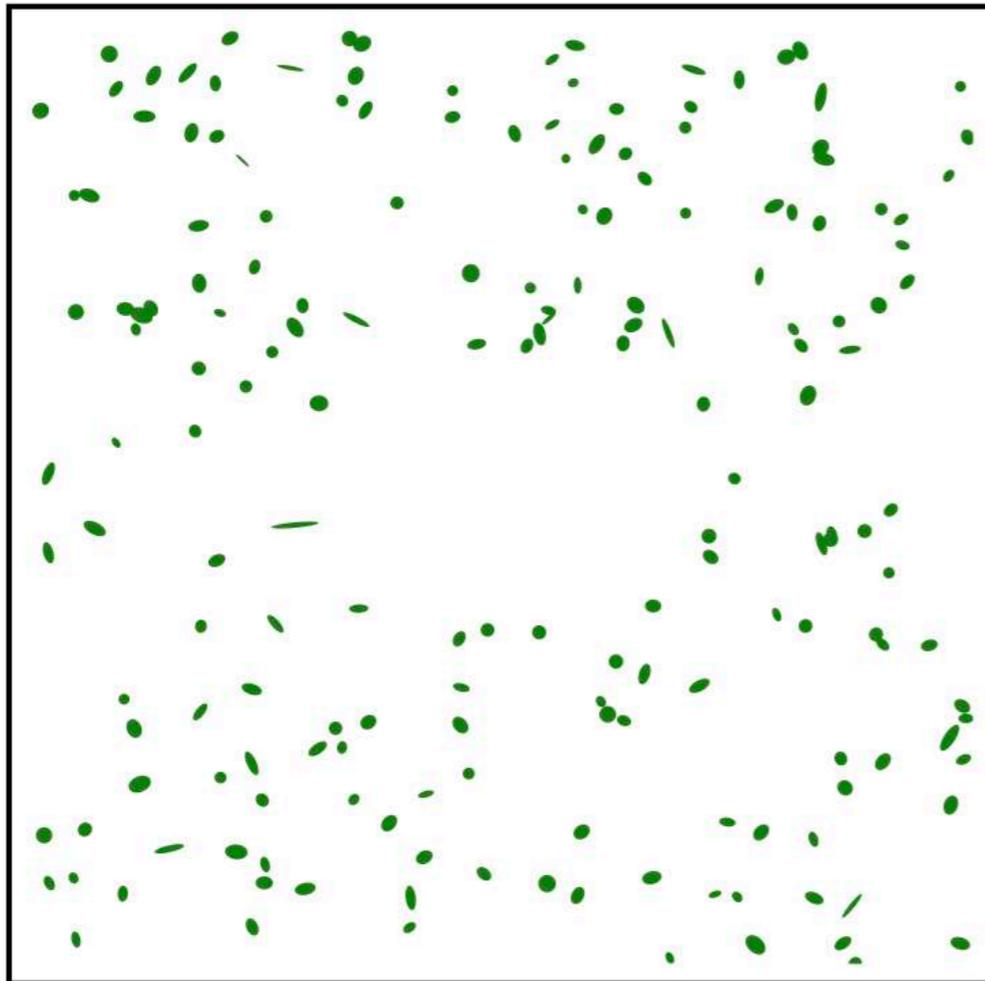

$\delta(z_l)$

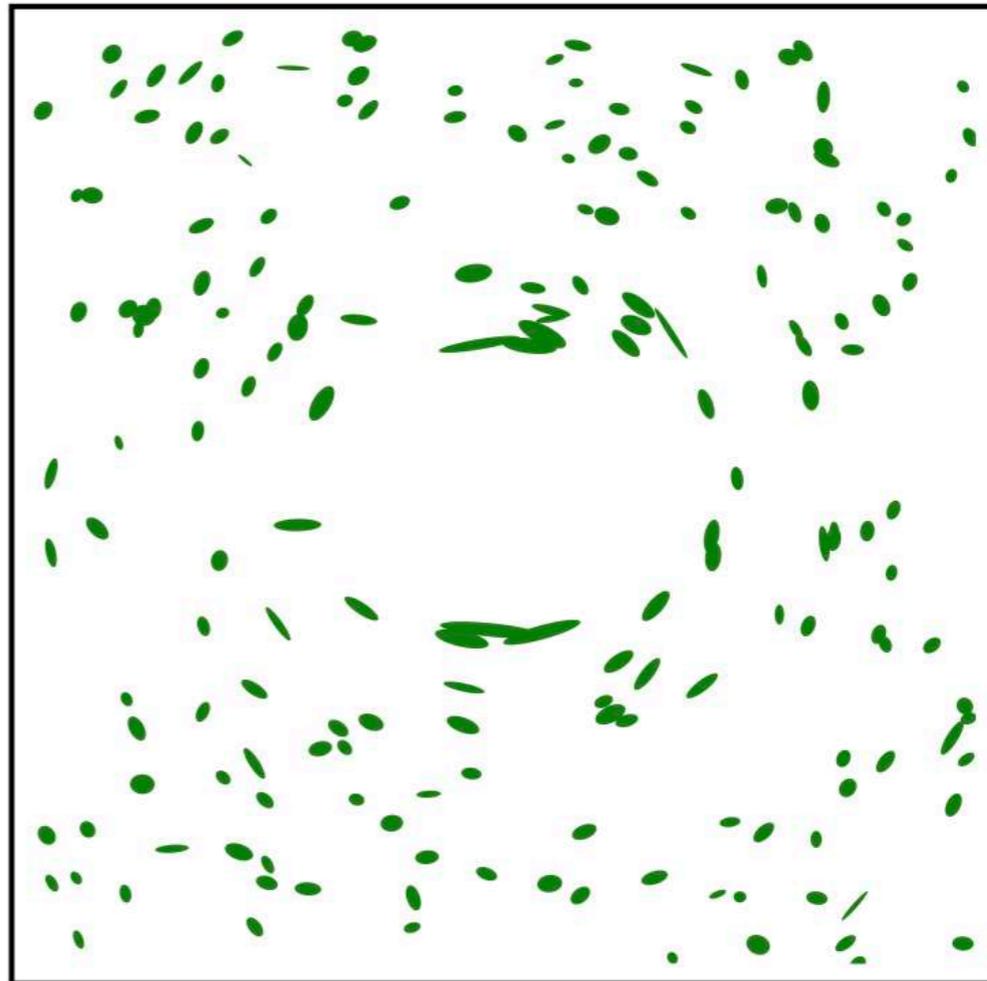

Direct measurement of matter distribution, including dark matter, around galaxy clusters

Mass Calibration by Weak Lensing

Unlensed

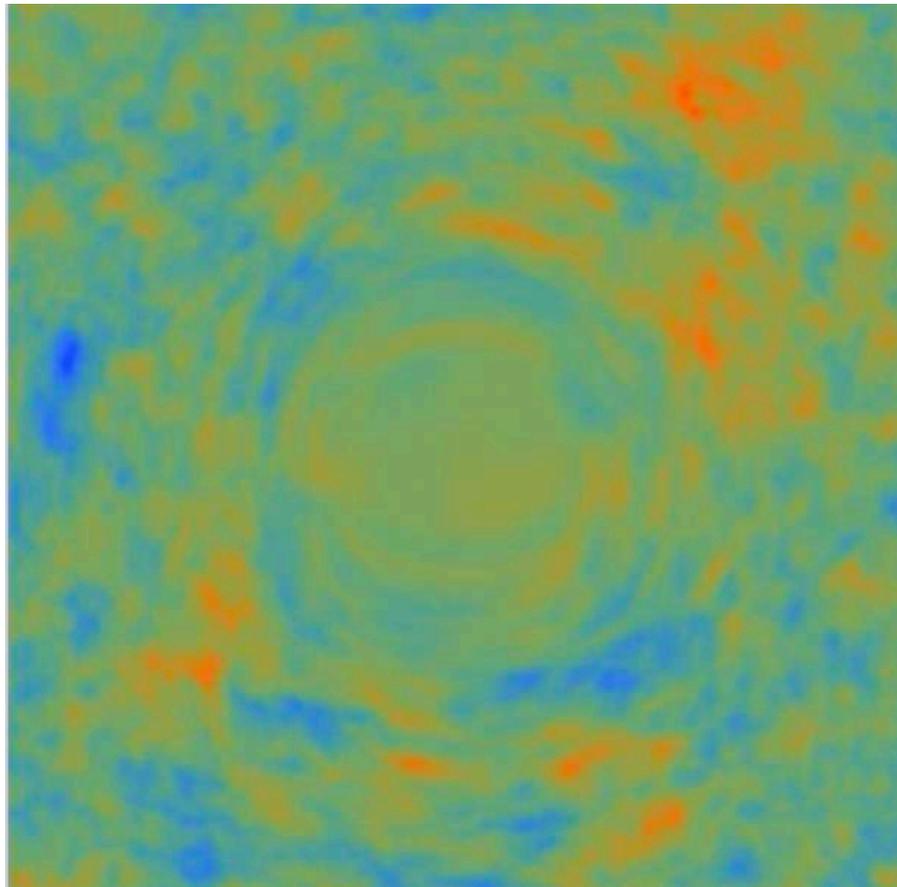

Lensed

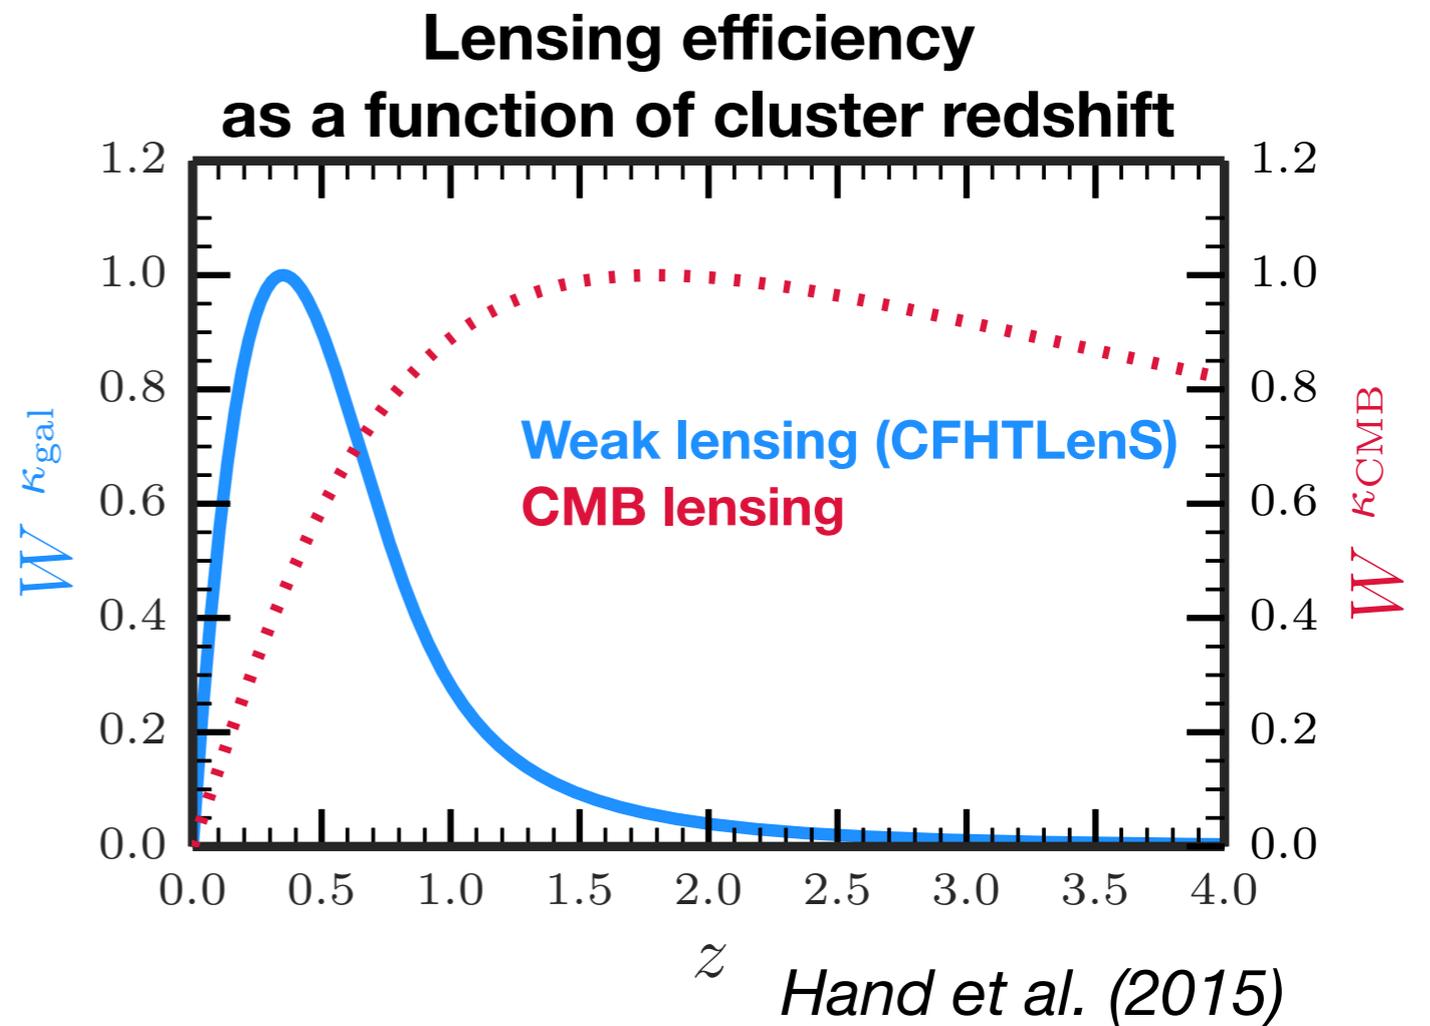

Weak lensing is the best tool to calibrate cluster mass, but we need a good telescope and instrument.

Mass Calibration by CMB Lensing

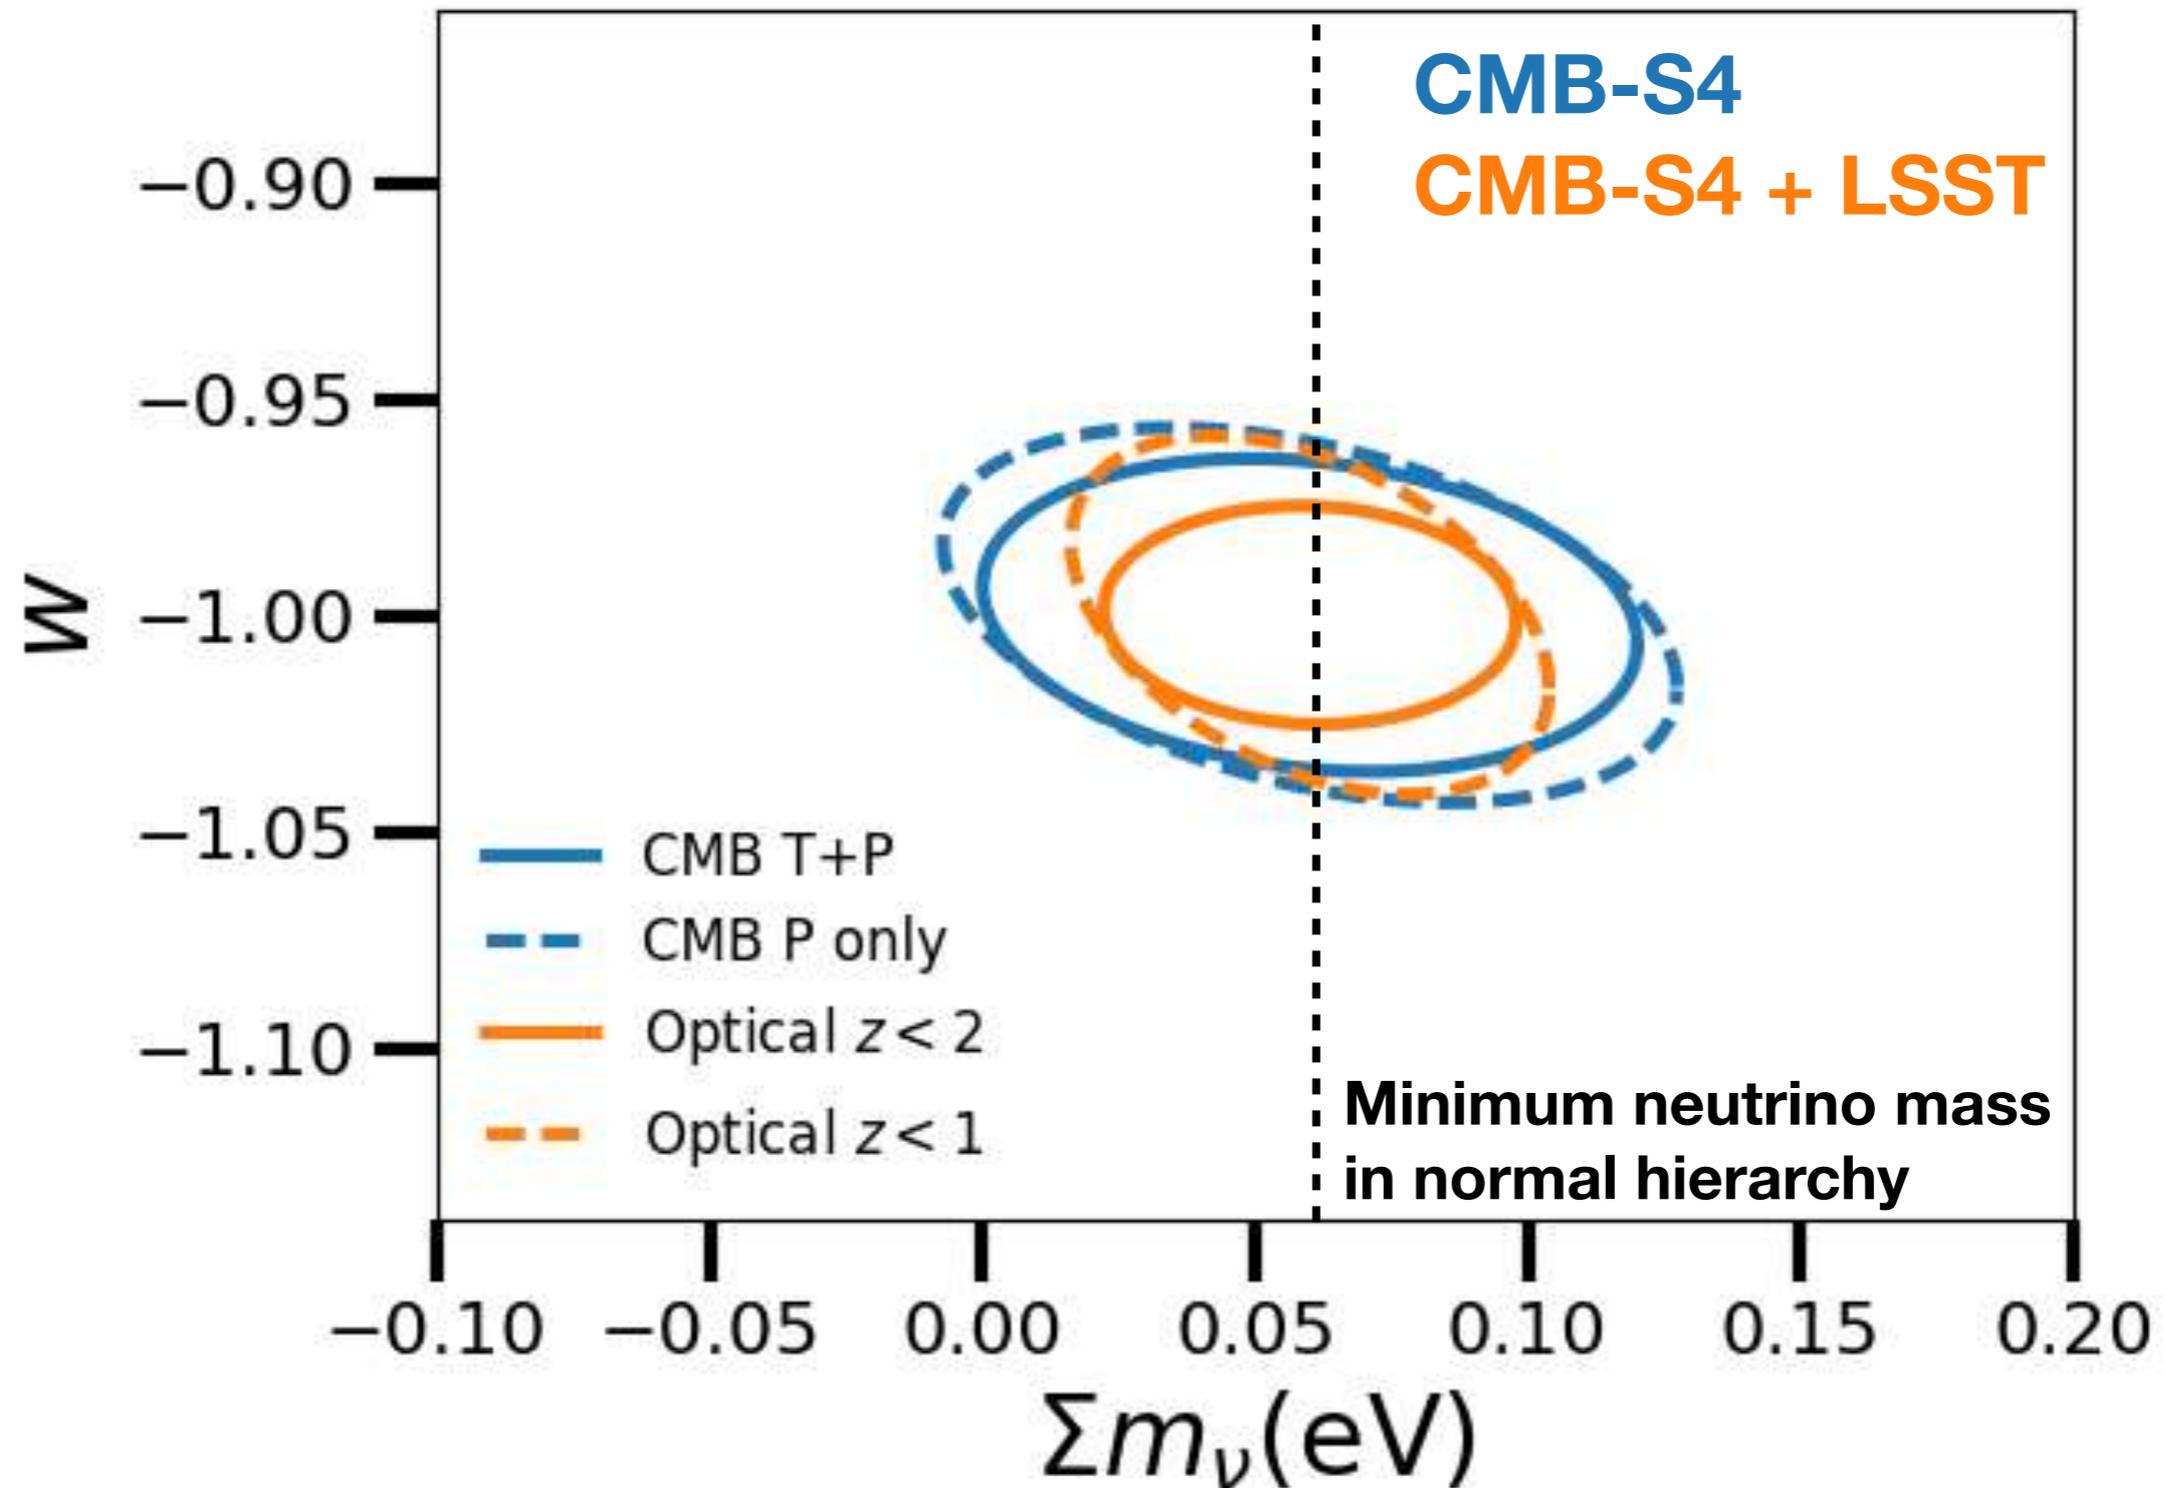

Credit: W. Hu

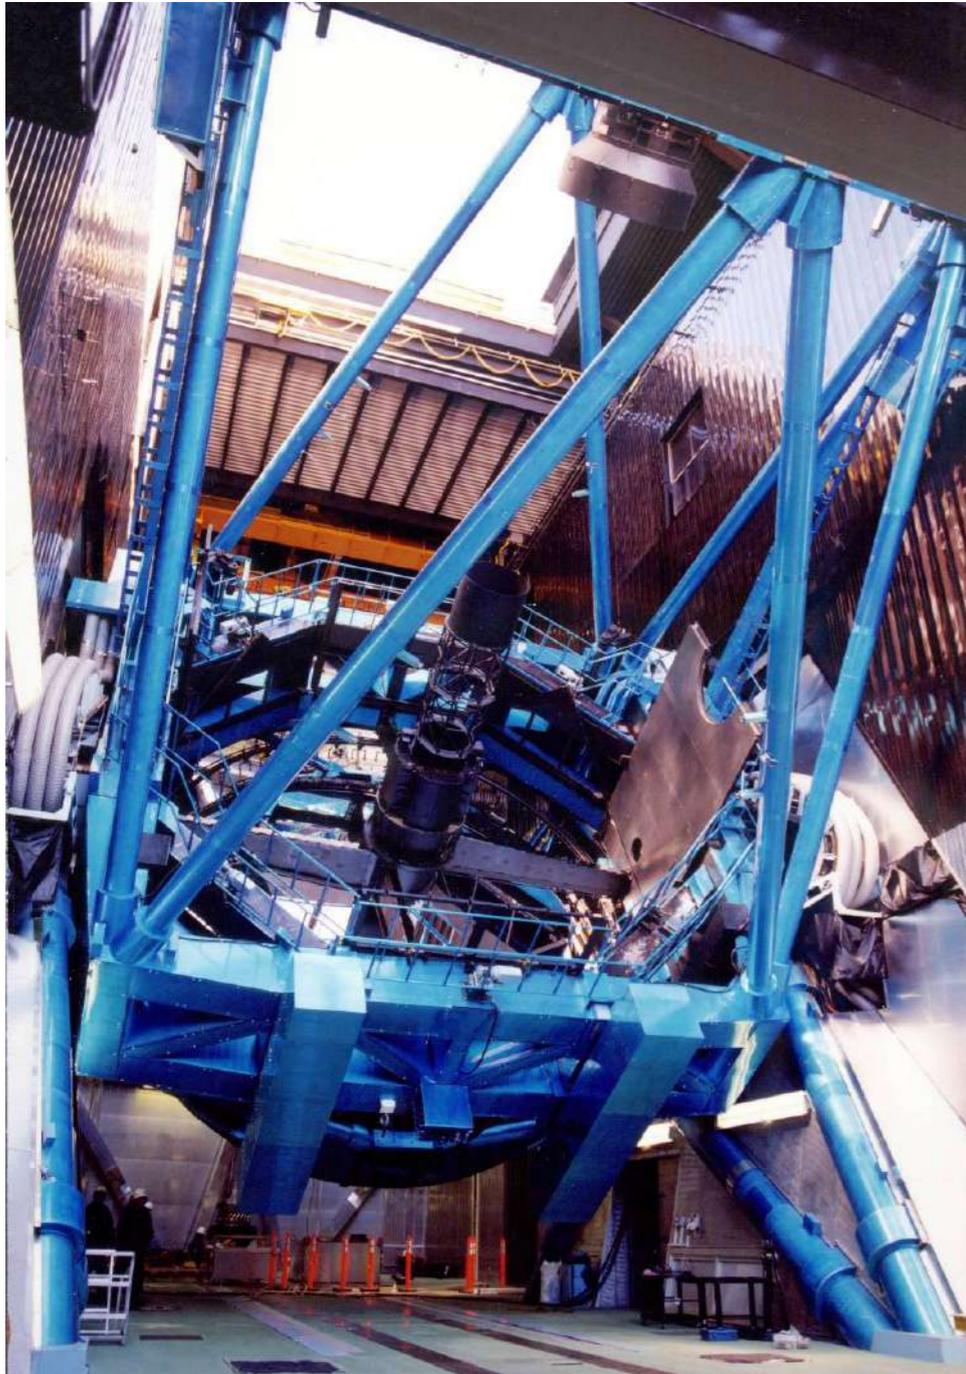

CMB lensing allows us to measure high- z cluster mass

What We Will See in 2020s

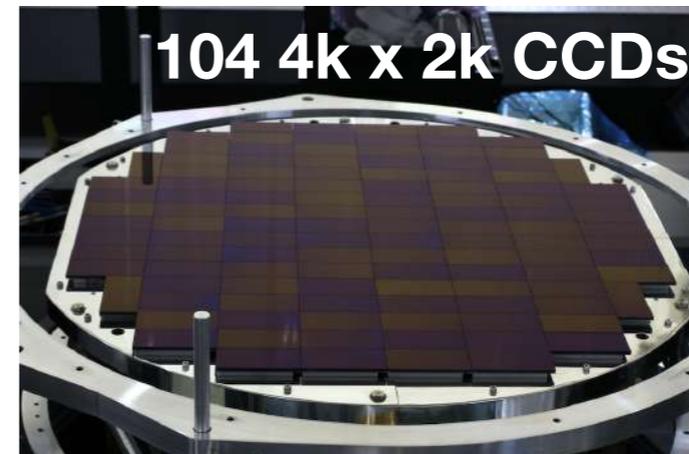

Subaru HSC

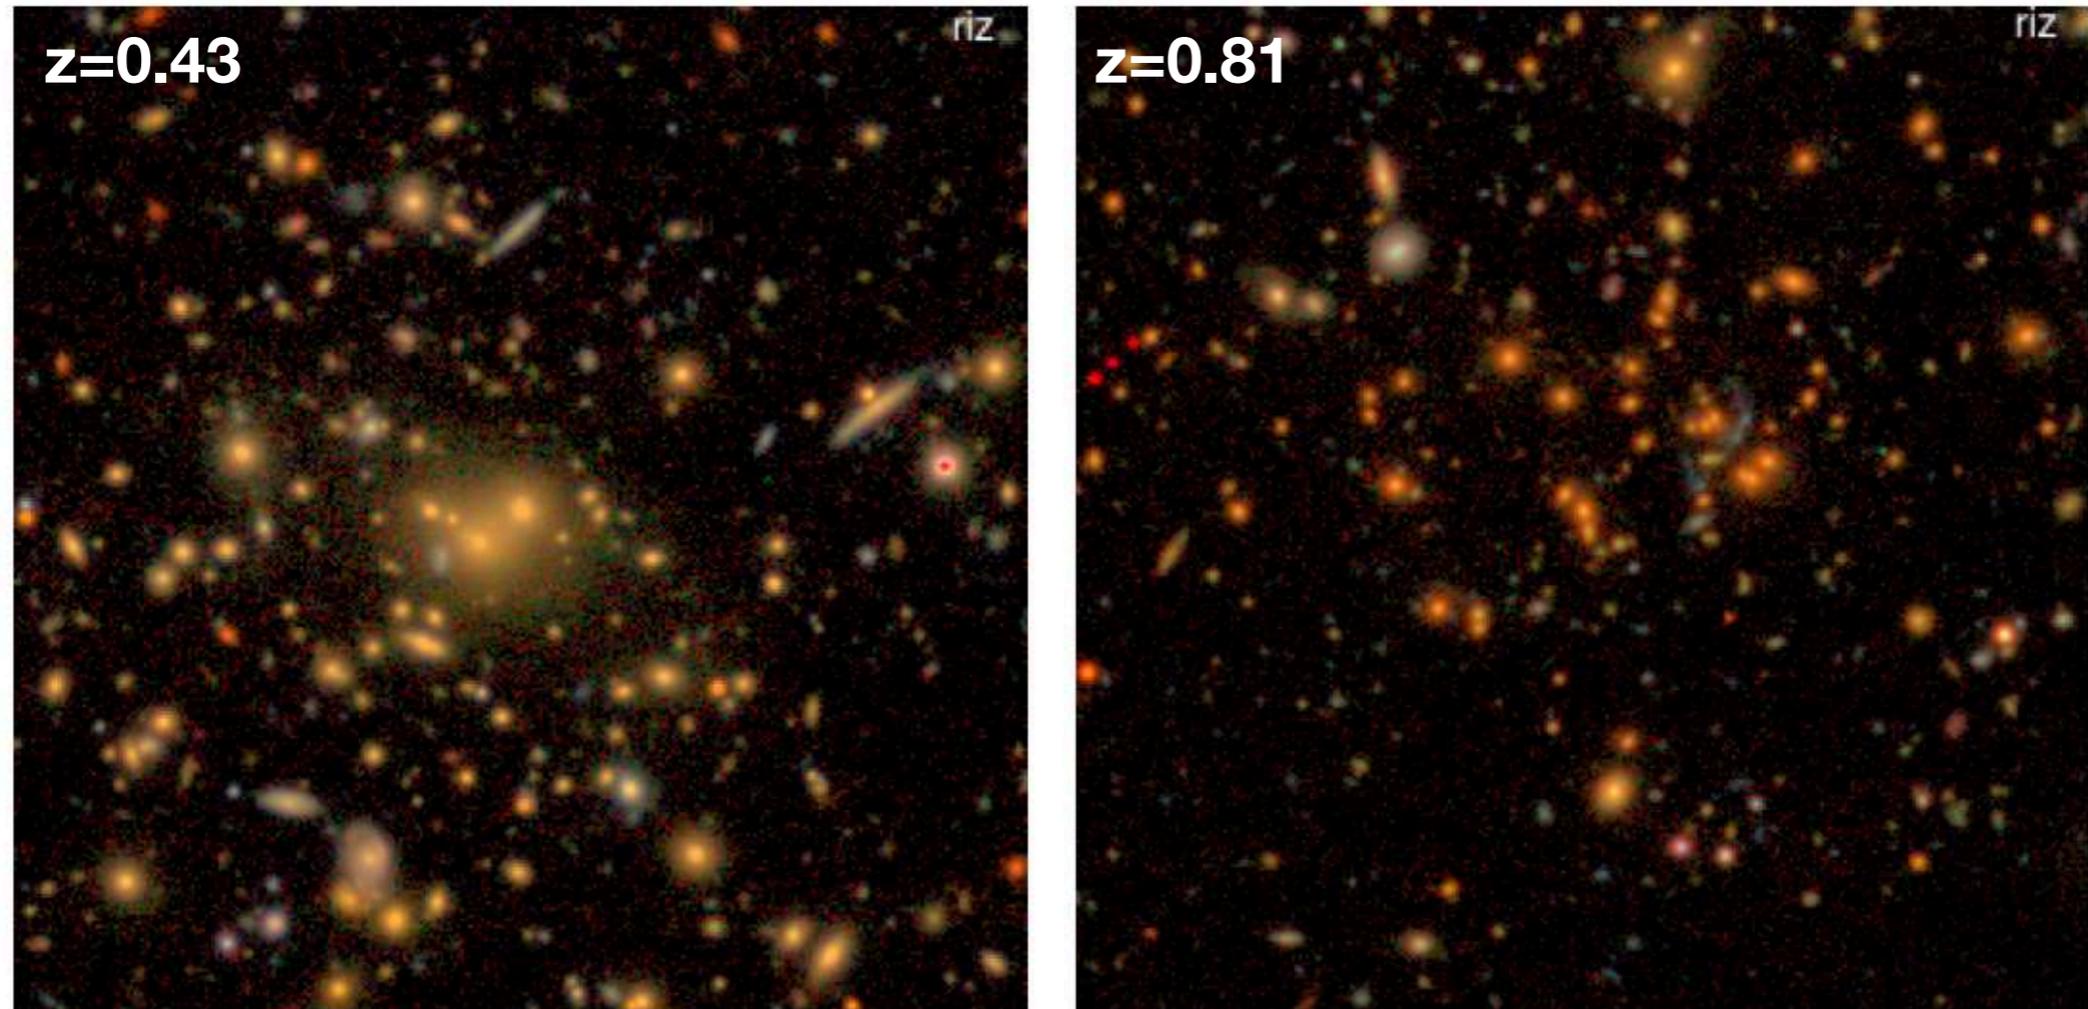

Credit: NAOJ

- Newly developed wide-field camera at the Subaru Telescope
- Best instrument for weak lensing
 - Light-gathering power: 8.2m primary mirror
 - Superb image quality: ~260 actuators
 - Large field-of-view: 1.8 deg²
- Wide-field survey started in 2014
 - Wide area: 1,400 deg²
 - Limiting magnitude: $i_{lim} \sim 26$

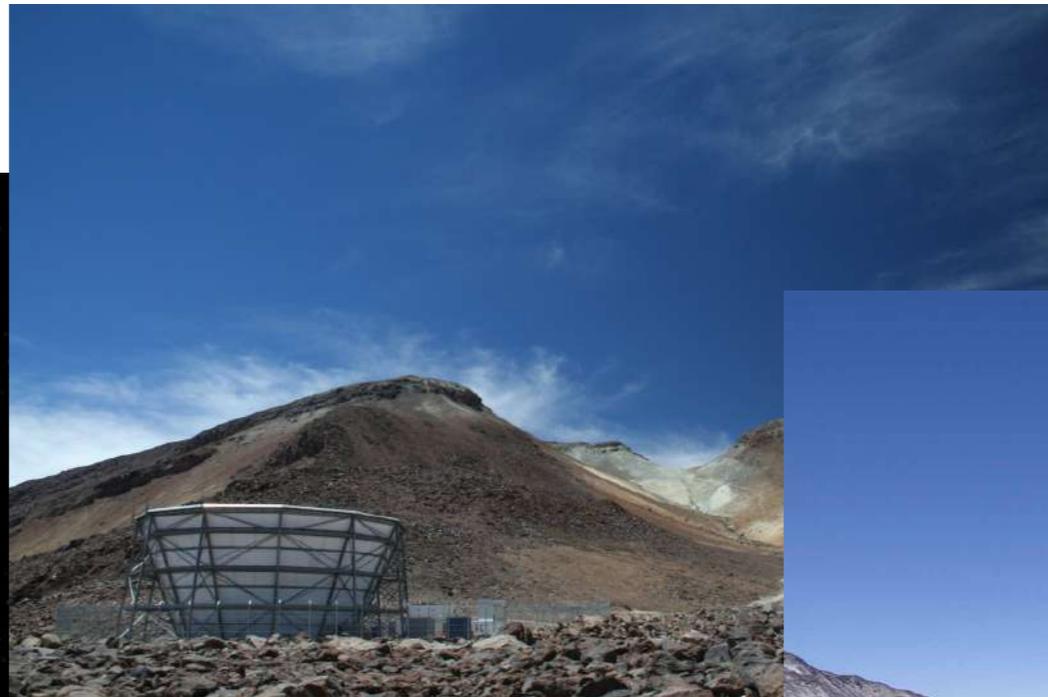

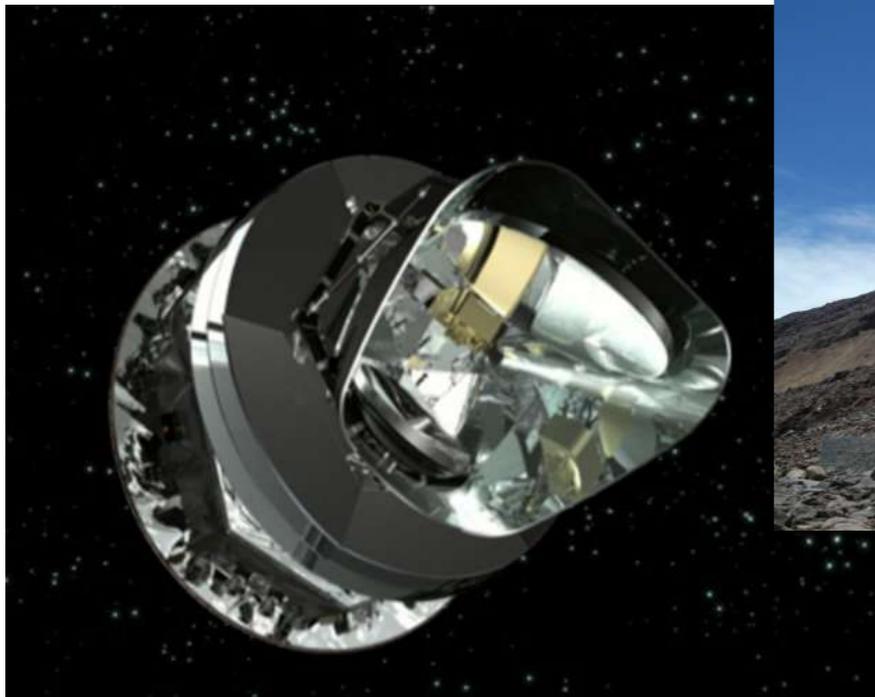

HSC CAMIRA Clusters

HSC can find galaxy clusters up to $z \sim 1.1$
(can be extended if NIR data is combined)

CMB Experiments

Planck Satellite

ACT

Simons Array

We have started looking into Planck CMB lensing by CAMIRA clusters

Summary

- Cluster number count is a powerful tool to constrain the total neutrino mass.
- Cluster mass should be calibrated to achieve a precision cluster cosmology.
- Optical weak lensing/CMB lensing is suitable for calibrating low- z /high- z cluster mass.
- We have started looking into Planck CMB lensing by HSC clusters!
