Pauli Exclusion Principle (PEP)

In its original form by Pauli:

“In an atom there cannot be two or more equivalent electrons for which the values of all four quantum numbers (n , l , m_l , m_s) coincide. If an electron exists in an atom for which all of these numbers have definite values, then this state is ‘occupied’.”

Then extended to all fermions

Feynman Lectures on Physics:

“Why is it that particles with half-integral spin are Fermi particles (...) whereas particles with integral spin are Bose particles (...)?

We apologize for the fact that we can not give you an elementary explanation. An explanation has been worked out by Pauli from complicated arguments from quantum field theory and relativity. He has shown that the two must necessarily go together, but we have not been able to find a way to reproduce his arguments on an elementary level.

It appears to be one of the few places in physics where there is a rule which can be stated very simply, but for which no one has found a simple and easy explanation. (...)

This probably means that we do not have a complete understanding of the fundamental principle involved.”

Pauli Exclusion Principle (PEP)

Several proofs exist in QFT which differ in clarity and quality of physical insight.

Proof of spin-statistics theorem by Lüders and Zumino

Postulates:

- 1 - The theory is invariant with respect to the proper inhomogeneous Lorentz group (includes translations, does not include reflections)
- 2 - Two operators of the same field at points separated by a spacelike interval either commute or anticommute (locality – microcausality)
- 3 - The vacuum is the state of lowest energy
- 4 - The metric of the Hilbert space is positive definite
- 5 - The vacuum is not identically annihilated by a field

From these postulates it follows that (pseudo)scalar fields commute and spinor fields anticommute.

(G. Lüders and B. Zumino, Phys. Rev. 110 (1958) 1450)

Pauli Exclusion Principle (PEP)

Theories of Statistics Violation

O.W. Greenberg: AIP Conf.Proc.545:113-127,2004

“Possible external *motivations for violation* of statistics include: (a) violation of *CPT*, (b) violation of *locality*, (c) violation of *Lorentz invariance*, (d) *extra space dimensions*, (e) *discrete space and/or time* and (f) *noncommutative spacetime*.....”

Ignatiev & Kuzmin model: Fermi oscillator with a third state

(Ignatiev, A.Y., Kuzmin, V., Quarks '86: Proceedings of the 229 Seminar, Tbilisi, USSR, 15-17 April 1986)

$$\begin{array}{ll} a^+|0\rangle = |1\rangle & a|0\rangle = 0 \\ a^+|1\rangle = \beta|2\rangle & a|1\rangle = |0\rangle \\ a^+|2\rangle = 0 & a|2\rangle = \beta|1\rangle \end{array}$$

β quantifies the degree of violation in the transition $|1\rangle \rightarrow |2\rangle$

Govorkov, A. can not be generalized to quantum field theory! Physics Letters A 1989, 236 137, 7-10.

Pauli Exclusion Principle (PEP)

- Greenberg, O.W.; Mohapatra, R.N.

Local Quantum Field Theory of Possible Violation of the Pauli Principle.

q parameter deforms anticommutators $a_k a_l^\dagger - q a_l^\dagger a_k = \delta_{k,l}$

Physical Review Letters 1987, 59, 2507

Govorkov, A. non relativistic! Physica A: Statistical Mechanics and its Applications 1994, 203, 655

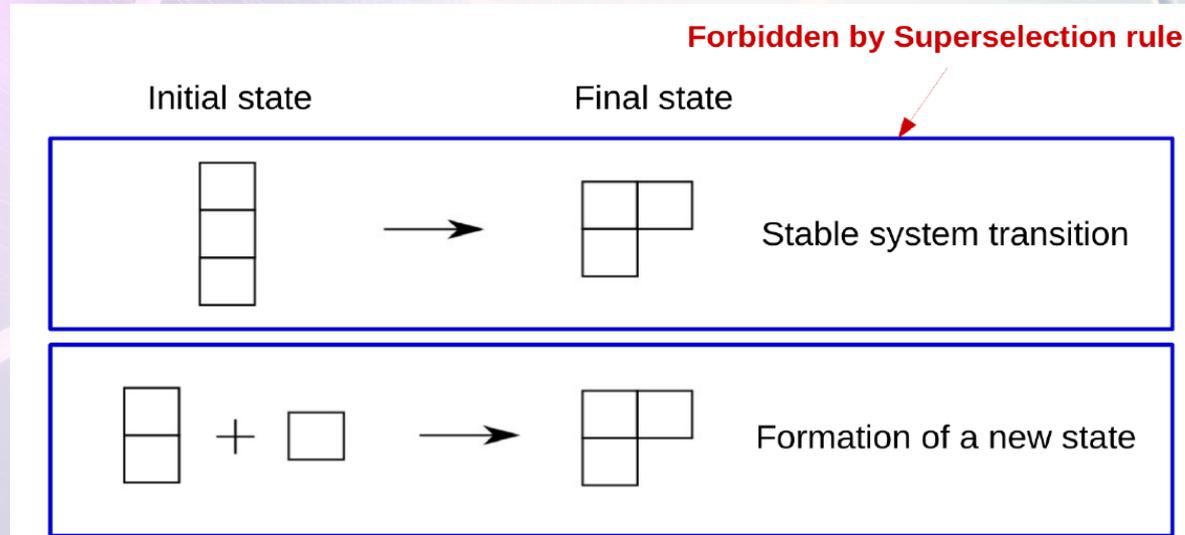

- In the absence of a complete relativistic theory alternative compatible with Quantum Mechanics → Rahal, V.; Campa, A. , Physical Review A (1988) 38, 3728

the global w. f. describing the totality of the electrons is not exactly antisymmetric → PEP mostly holds as long as the number of wrongly entangled pairs is small.

The non-Paulian character is intrinsic of the global w. f. → can be tested looking for signature of a violating interaction of a wrongly entangled pair.

Messiah - Greenberg superselection rule

Superpositions of states with different symmetry are not allowed →
 transition probability between two symmetry states is ZERO

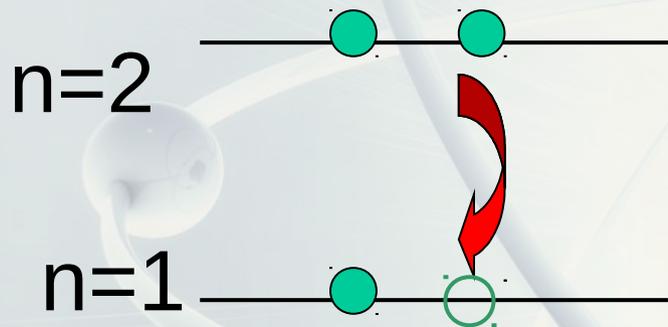

Process	MG conform	Limit for PEP violation	Experiment
anomalous atomic transition	Yes	4.7×10^{-29}	VIP [4]
anomalous atomic transition	No	1.3×10^{-47}	DAMA/LIBRA [5]
anomalous nuclear transition	No	2.2×10^{-57}	Borexino [6]

The VIP experiment sets lowest limit in an experiment in accordance with the MG superselection rule.

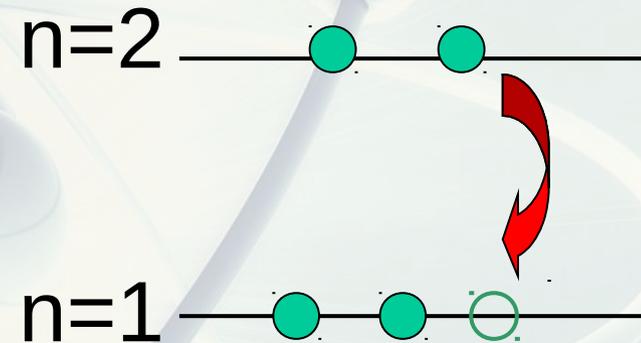

Experimental method:

Search for anomalous X-ray transitions
when bringing “new” electrons

Normal 2p → 1s
transition

Energy 8.04 keV

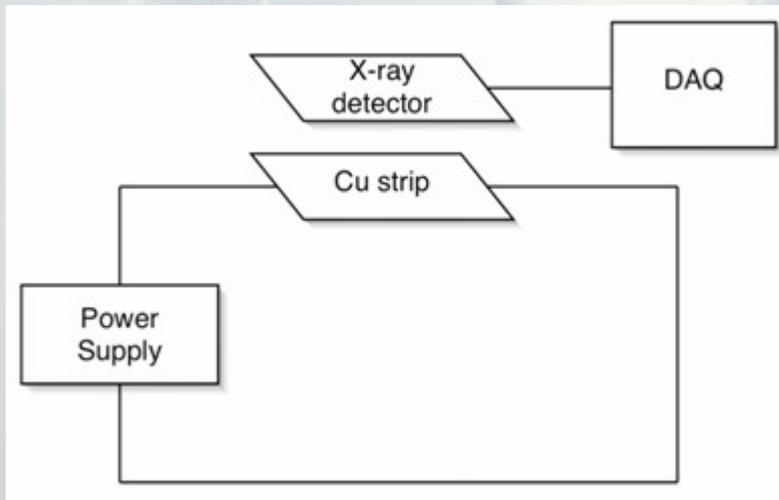

2p → 1s transition
violating
Pauli principle

Energy 7.7 keV

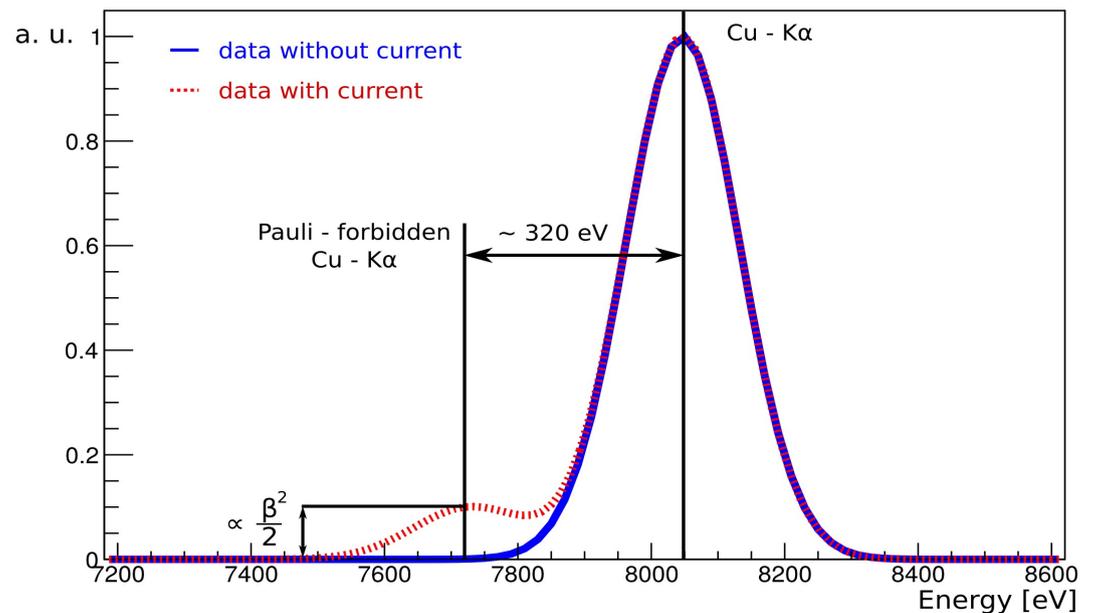

Pre-VIP : Ramberg and Snow (RS)

Phys. Lett. B238 (1990) 438

Search for anomalous electronic transitions in Cu induced by a circulating current (“new” external electrons, which interact with the valence electrons), namely transition from 2p to 1s already filled by 2 electrons, alternated to X-ray background measurements without current

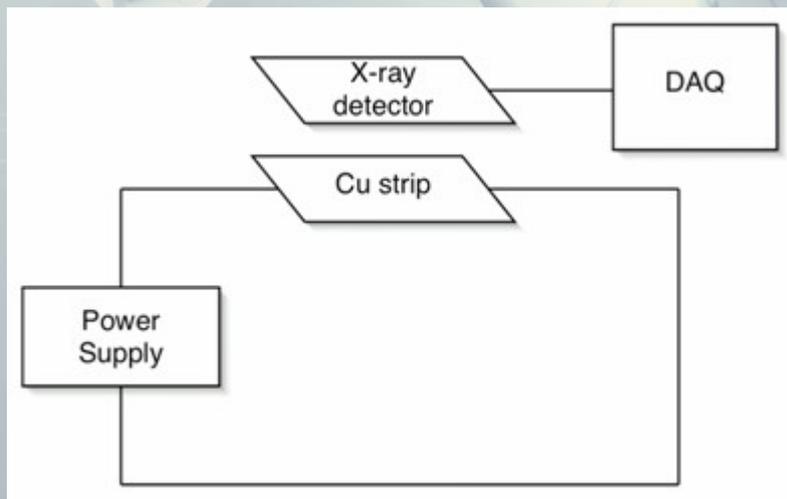

Undesired result :

Pre-VIP : Ramberg and Snow (RS)

Phys. Lett. B238 (1990) 438

Search for anomalous electronic transitions in Cu induced by a circulating current (“new” external electrons, which interact with the valence electrons), namely transition from 2p to 1s already filled by 2 electrons, alternated to X-ray background measurements without current

$$N_X \geq \beta^2 (0.90 \cdot 10^{28})$$
$$\beta^2 / 2 \leq 1.7 \cdot 10^{-26} (>95 \text{ C.L.})$$

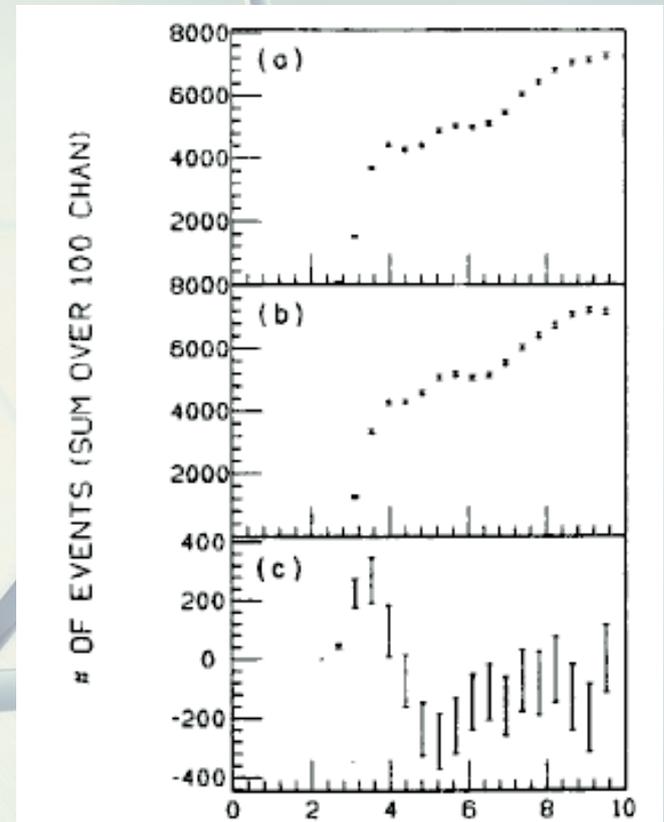

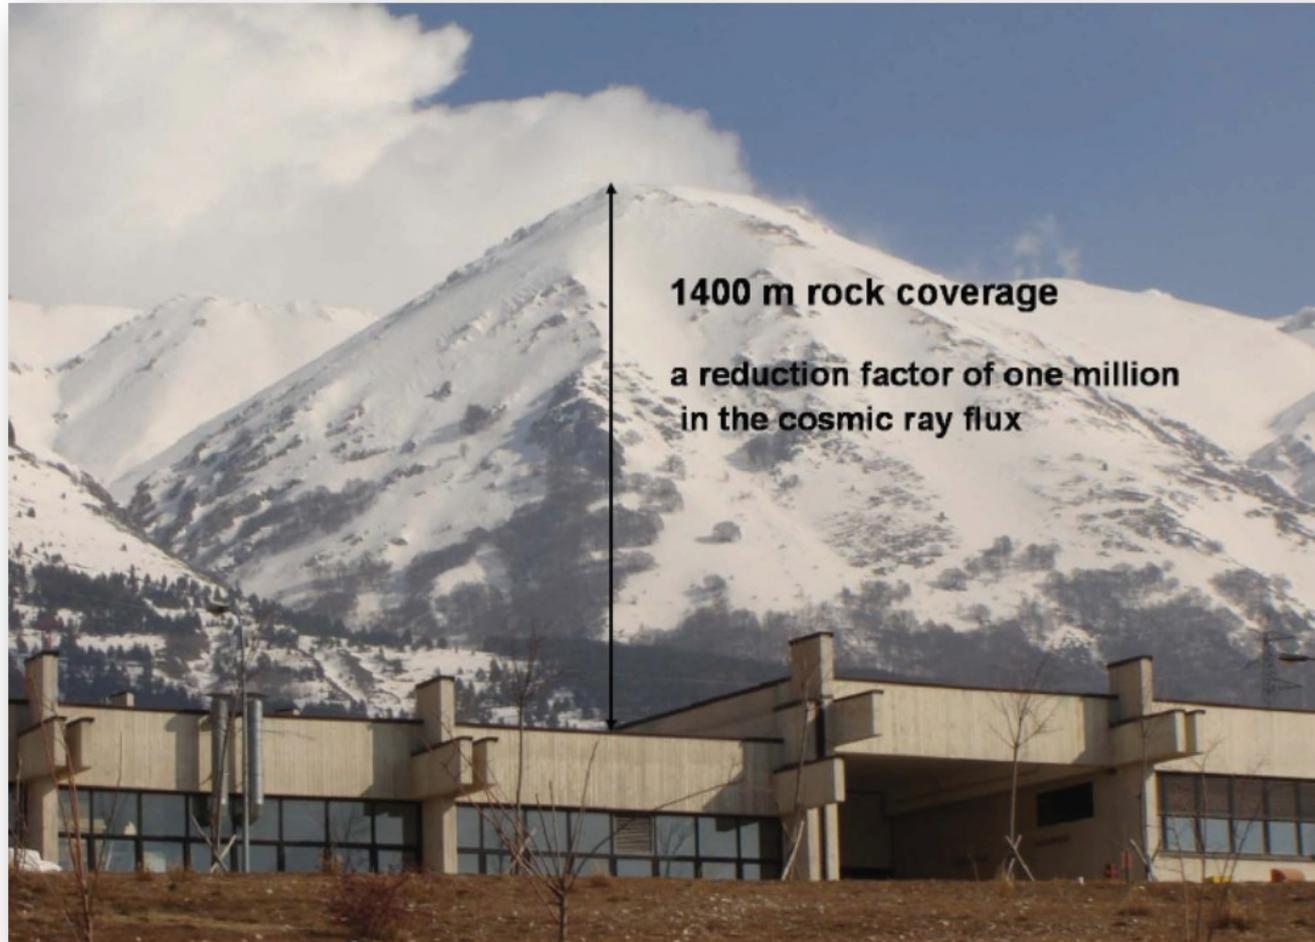

Fig. 2. (a) Number of triggers summed over 100 ADC channels, plotted versus equivalent X-ray energy with current-on in copper strip below X-ray counter. (Note the points are separated by 50 channels, so that only every other point is statistically independent). (b) Same as (a) but with no current passing through an identical strip of copper. (c) Difference between (a) and (b) after normalization at the 9.5 keV point.

VIP Experiment & LNGS

VIP Experiment & LNGS

Goal: improve the R&S PEP violation limit ($\beta^2/2 < 1.7 \times 10^{-26}$) by 3-4 orders of magnitude!

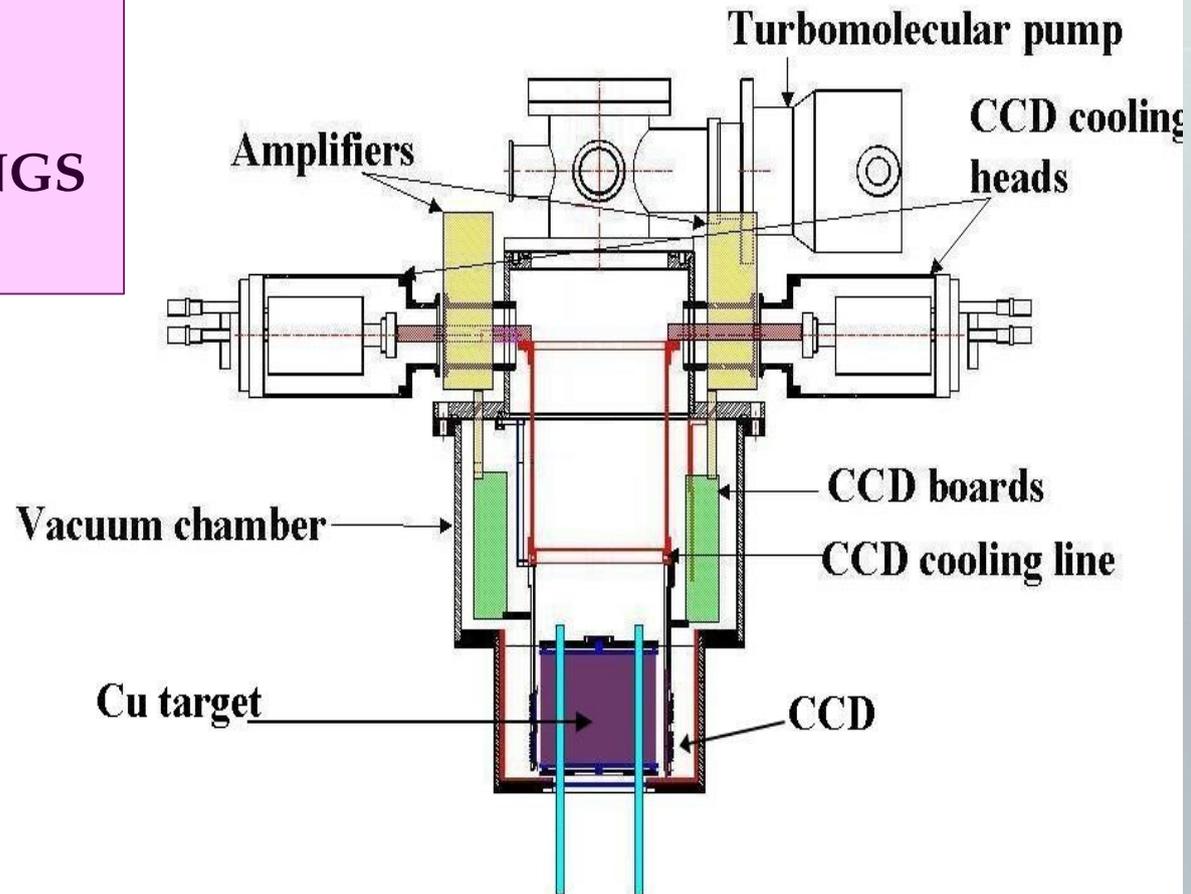

VIP setup: a) copper ultrapure cylindrical foil b) surrounded by 16 Charge Coupled Devices (CCD)

c) inside a vacuum chamber: CCDs cooled to 168K by a cryogenic system

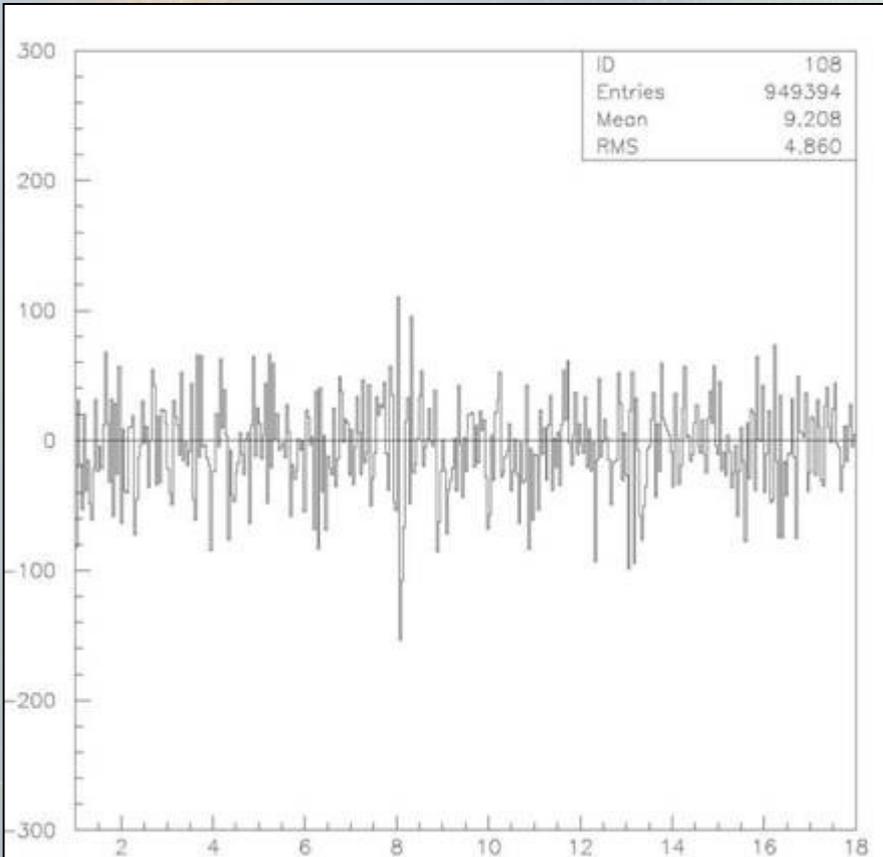

d) amplifiers + read out ADC boards.

Advantages

- High resolution CCDs
- Low background environment LNGS
- High statistics.

VIP Experiment

PEP violation
Probability:

After about 2 years running

$$\beta^2/2 < 4.7 \times 10^{-29}$$

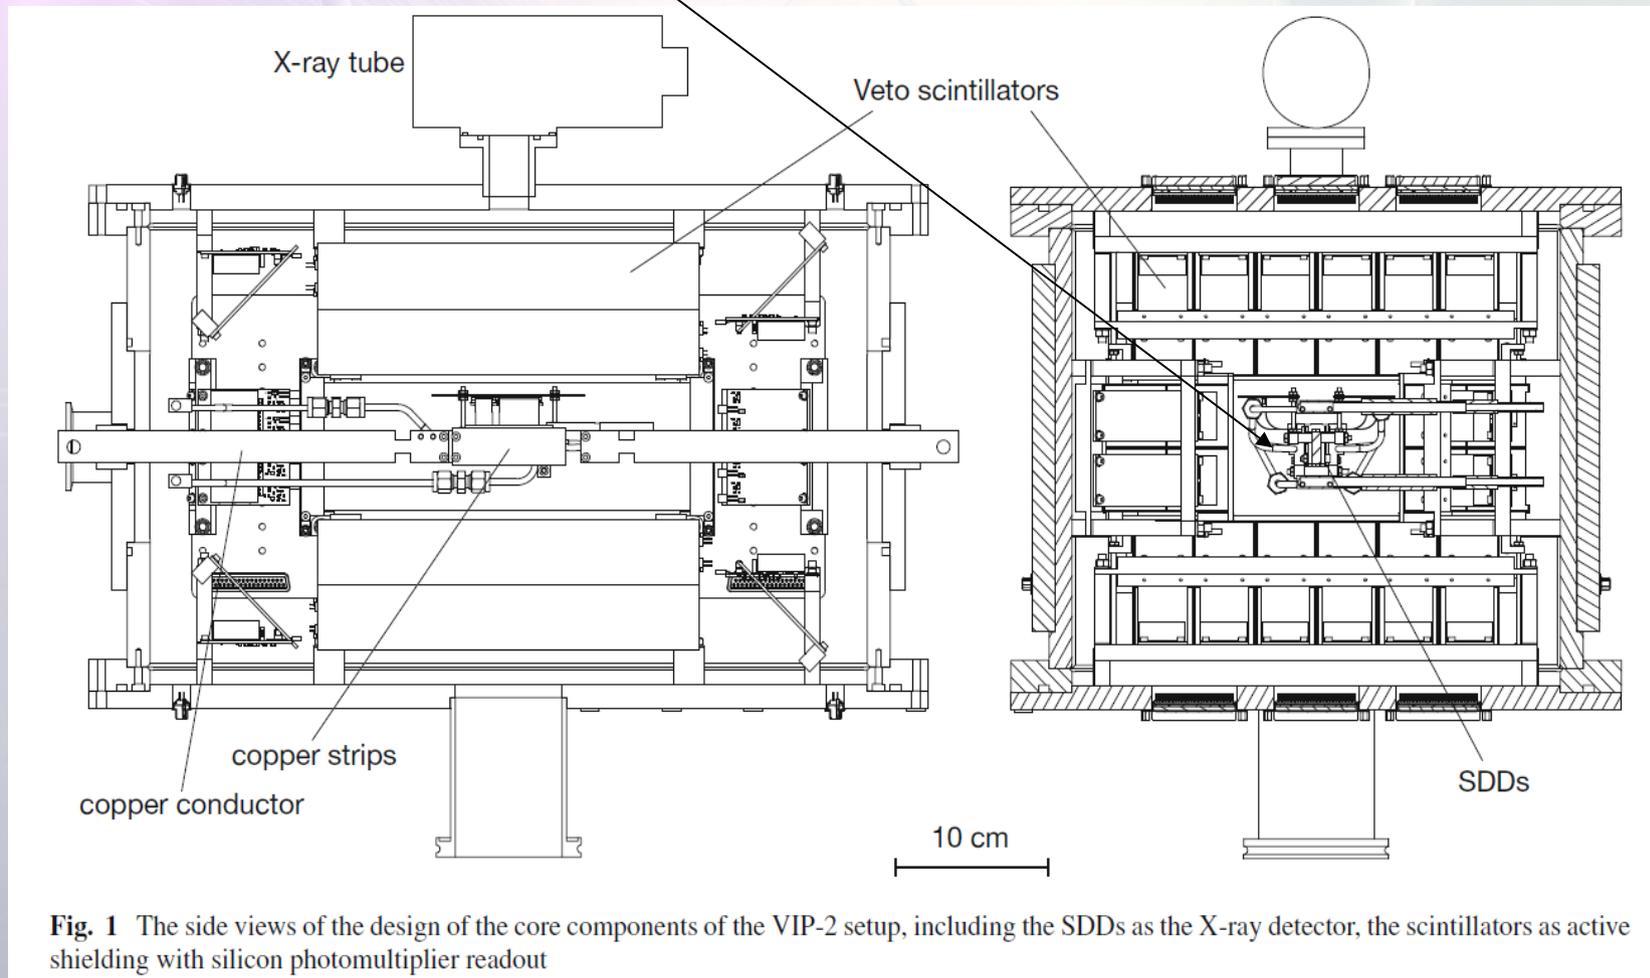

(Preliminary)

*We have thus improved the limit obtained by Ramberg & Snow
by a factor 400*

(Foundation of Physics 41 (2011) 282+ other papers)

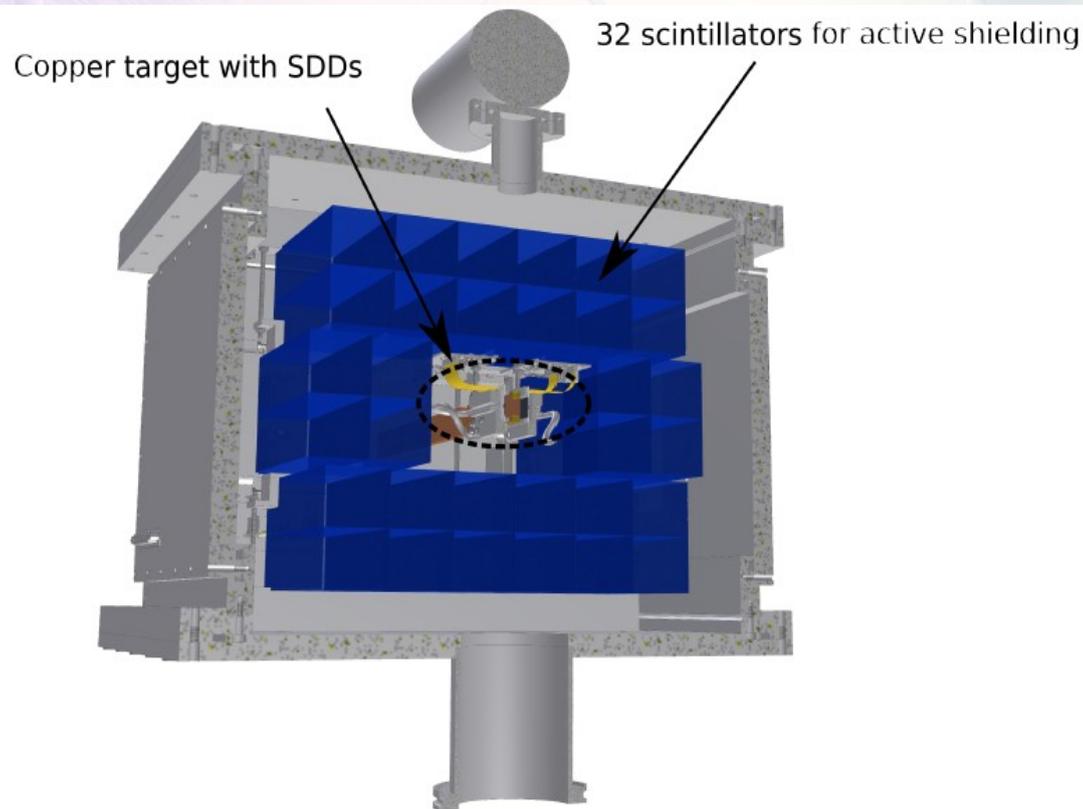

VIP-2 goal 2 OM improvement

a) Silicon Drift Detectors (SDDs) → higher resolution, faster (triggerable) detectors

VIP-2 goal 2 OM improvement

b) VETO system (32 plastic scintillators + SiPMs read out) → rejection of background (high energy charged particles) from outside the detector

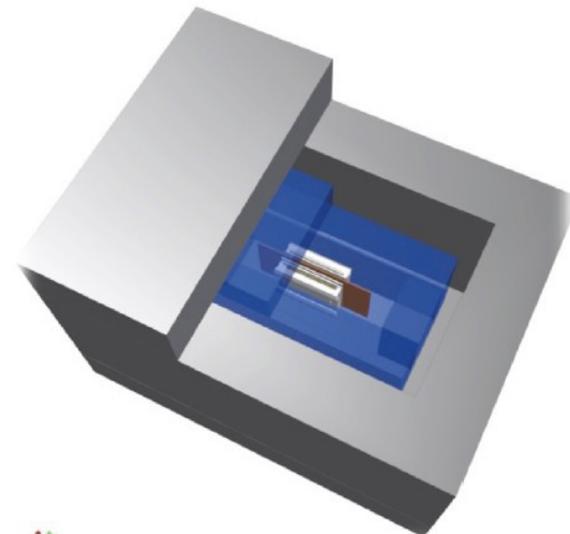

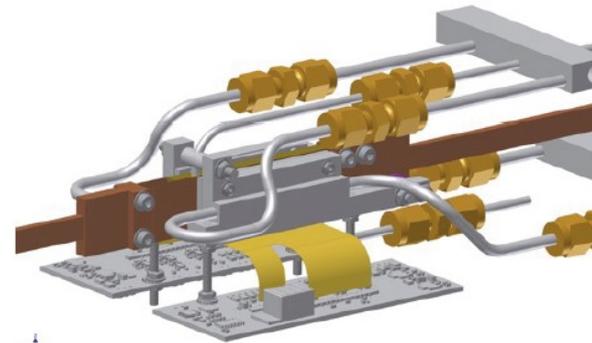

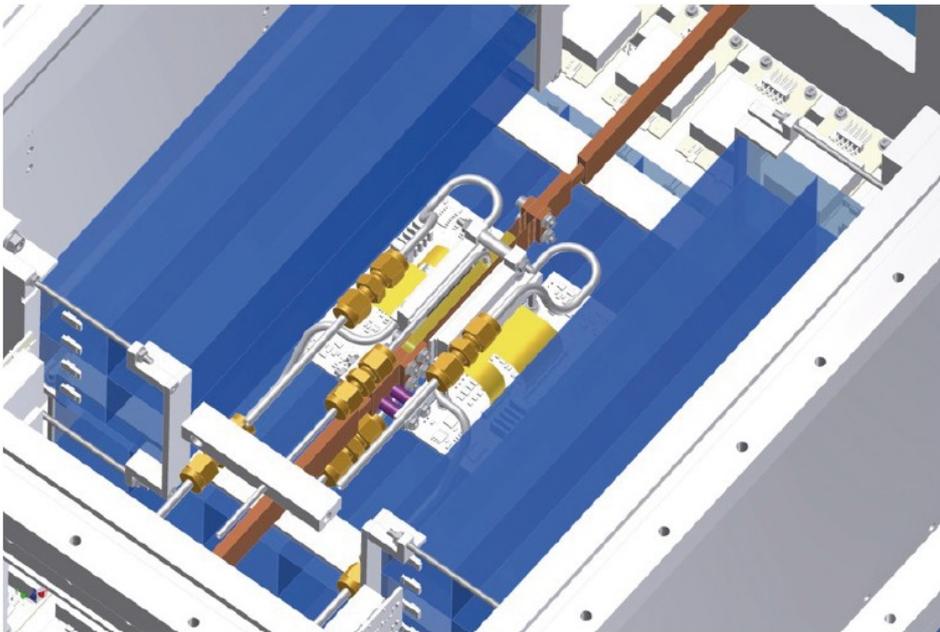

32 scintillators (blue) read out by two Silicon Photomultipliers each, are installed around the SDDs to give an active veto signal.

VIP-2 goal 2 OM improvement

c) more compact target → higher acceptance

d) Cu strips cooled by a closed Fryka chiller circuit → higher current (100 A) @ 20 °C of Cu target implies 1 °K heating in SDDs

Sketch of the VIP2 Setup:

VIP-2 goal 2 OM improvement

e) quick (one hour) resolution and energy calibration. X-ray tube irradiates zirconium & titanium

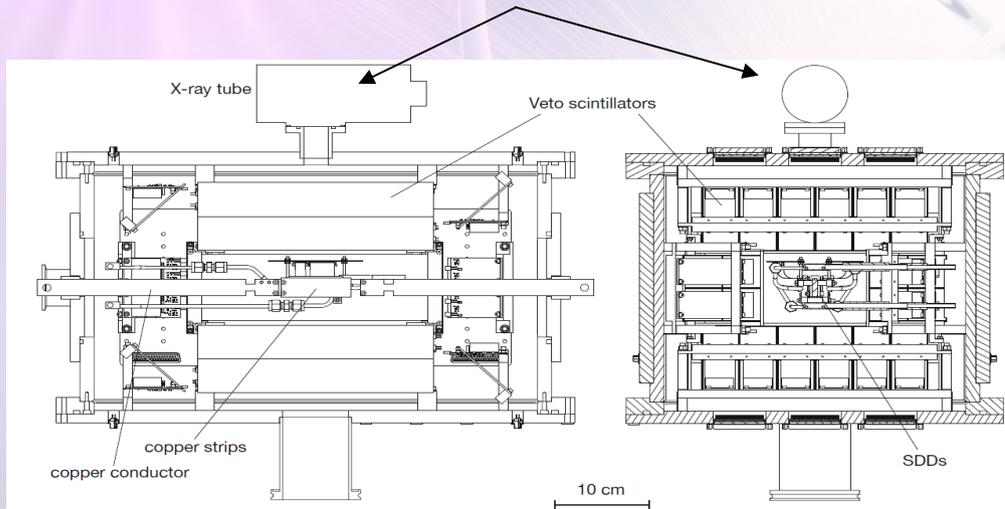

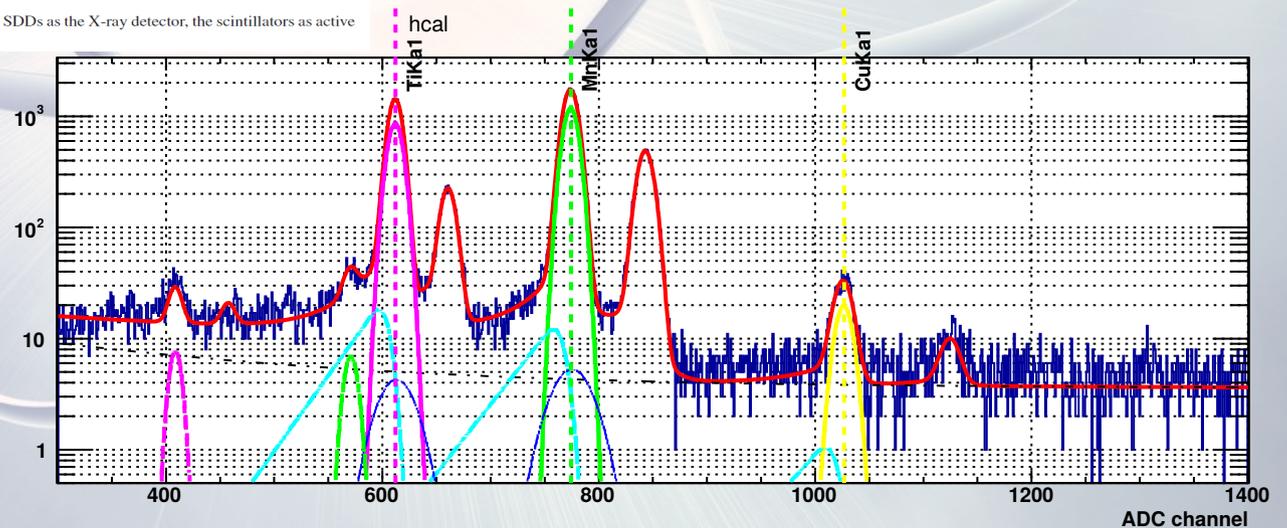

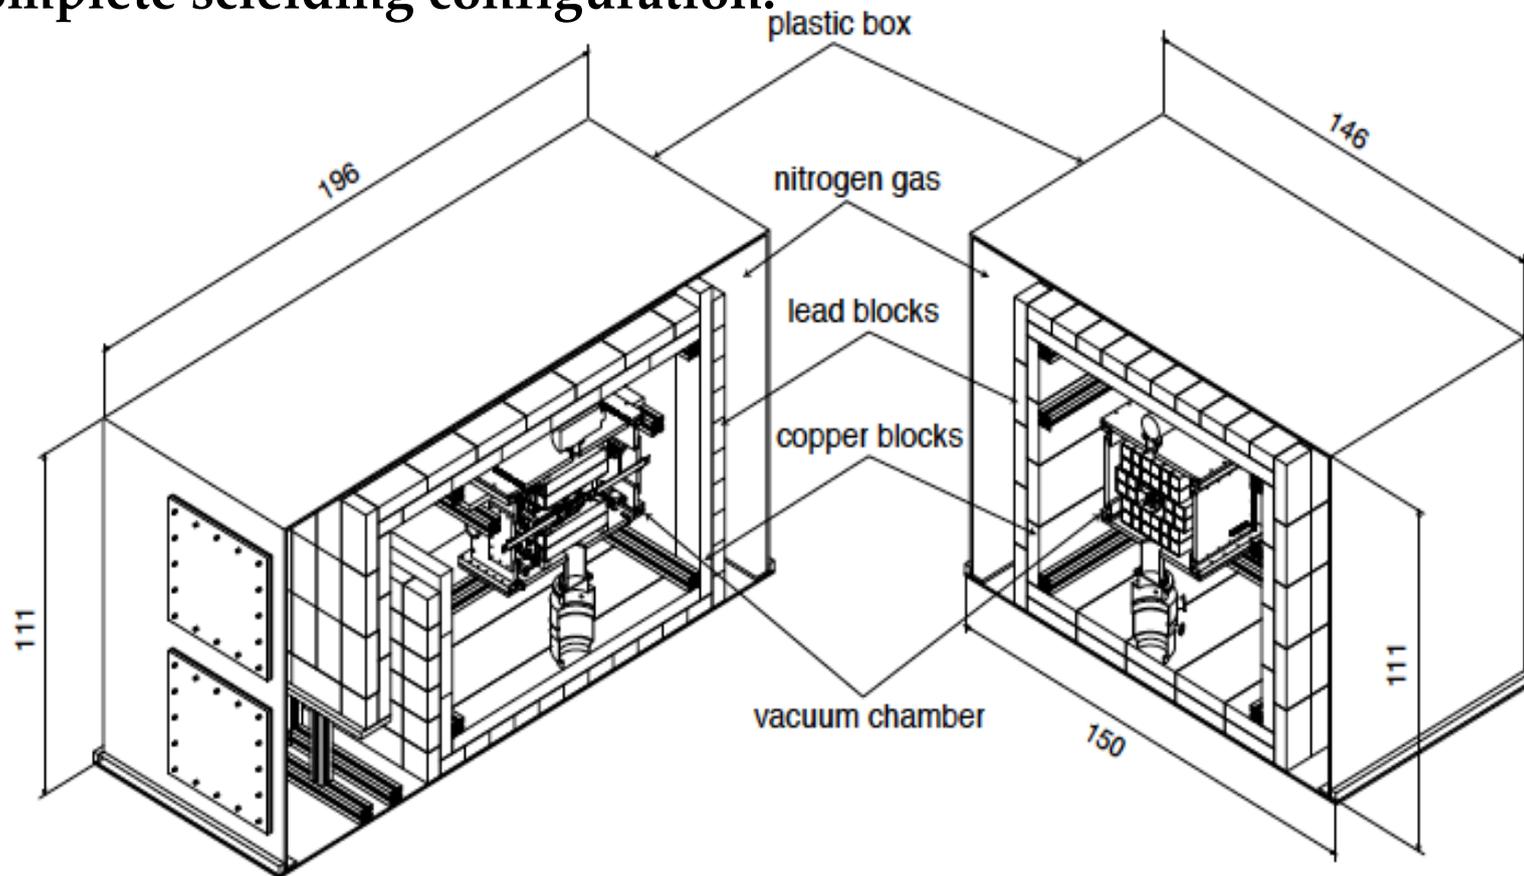

Fig. 1 The side views of the design of the core components of the VIP-2 setup, including the SDDs as the X-ray detector, the scintillators as active shielding with silicon photomultiplier readout

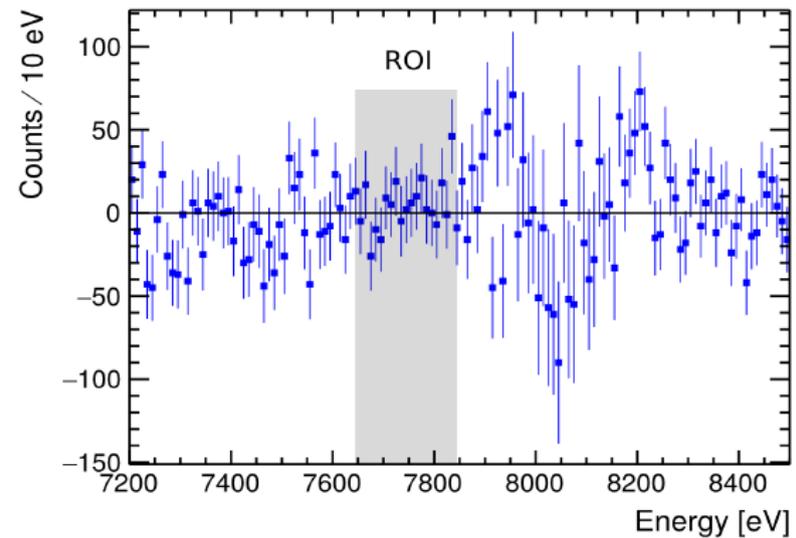

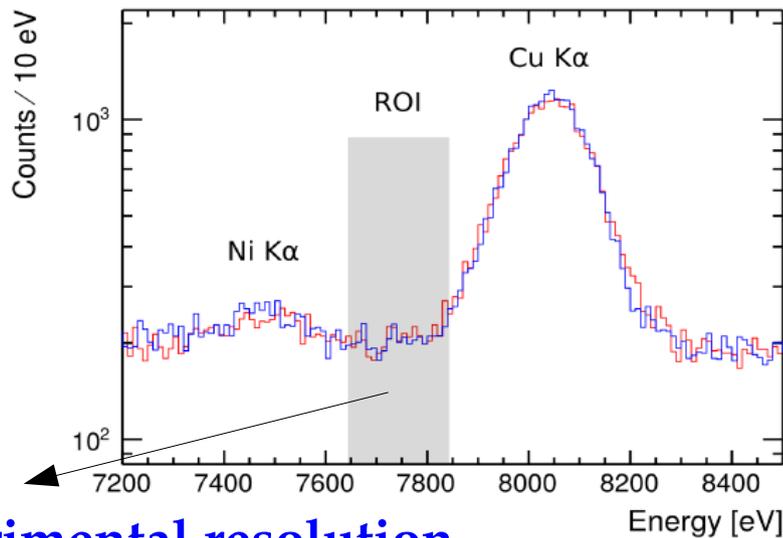

- SDD calibration spectrum at 125 K
- Energy resolution 150 eV (FWHM) for Mn K α

VIP-2 goal 2 OM improvement

Complete shielding configuration:

pre-VIP-2 (w.o. shielding) results

experimental resolution

The data measured at LNGS with current (red) and without current (blue) on the left side. The subtracted spectrum is shown on the right. No excess of events is found in the region of interest (ROI - grey) of the searched PEP violating.

3s of the subtracted number of counts in the ROI

$$\Delta N_x \geq \frac{\beta^2}{2} \frac{1}{10} \frac{D \sum (I \Delta t)}{\mu e} \text{ (detection efficiency)}$$

$$\frac{\beta^2}{2} \leq \frac{10 \mu e}{D \sum (I \Delta t)} \frac{\Delta N_x}{\text{(detection efficiency)}}$$

$$\frac{\beta^2}{2} \leq \frac{3 \times 91}{1.46 \times 10^{31}} = 1.87 \times 10^{-29}$$

mean free path μ	target length D	current I	data taking time Δt	detection efficiency

factor 2.5 gain respect to VIP

pre-VIP-2 (w.o. shielding) results

Same data set - simultaneous fit of the “sig + bkg” and bkg spectra, in order to use all the information available for the background shape from the data. The obtained fits:

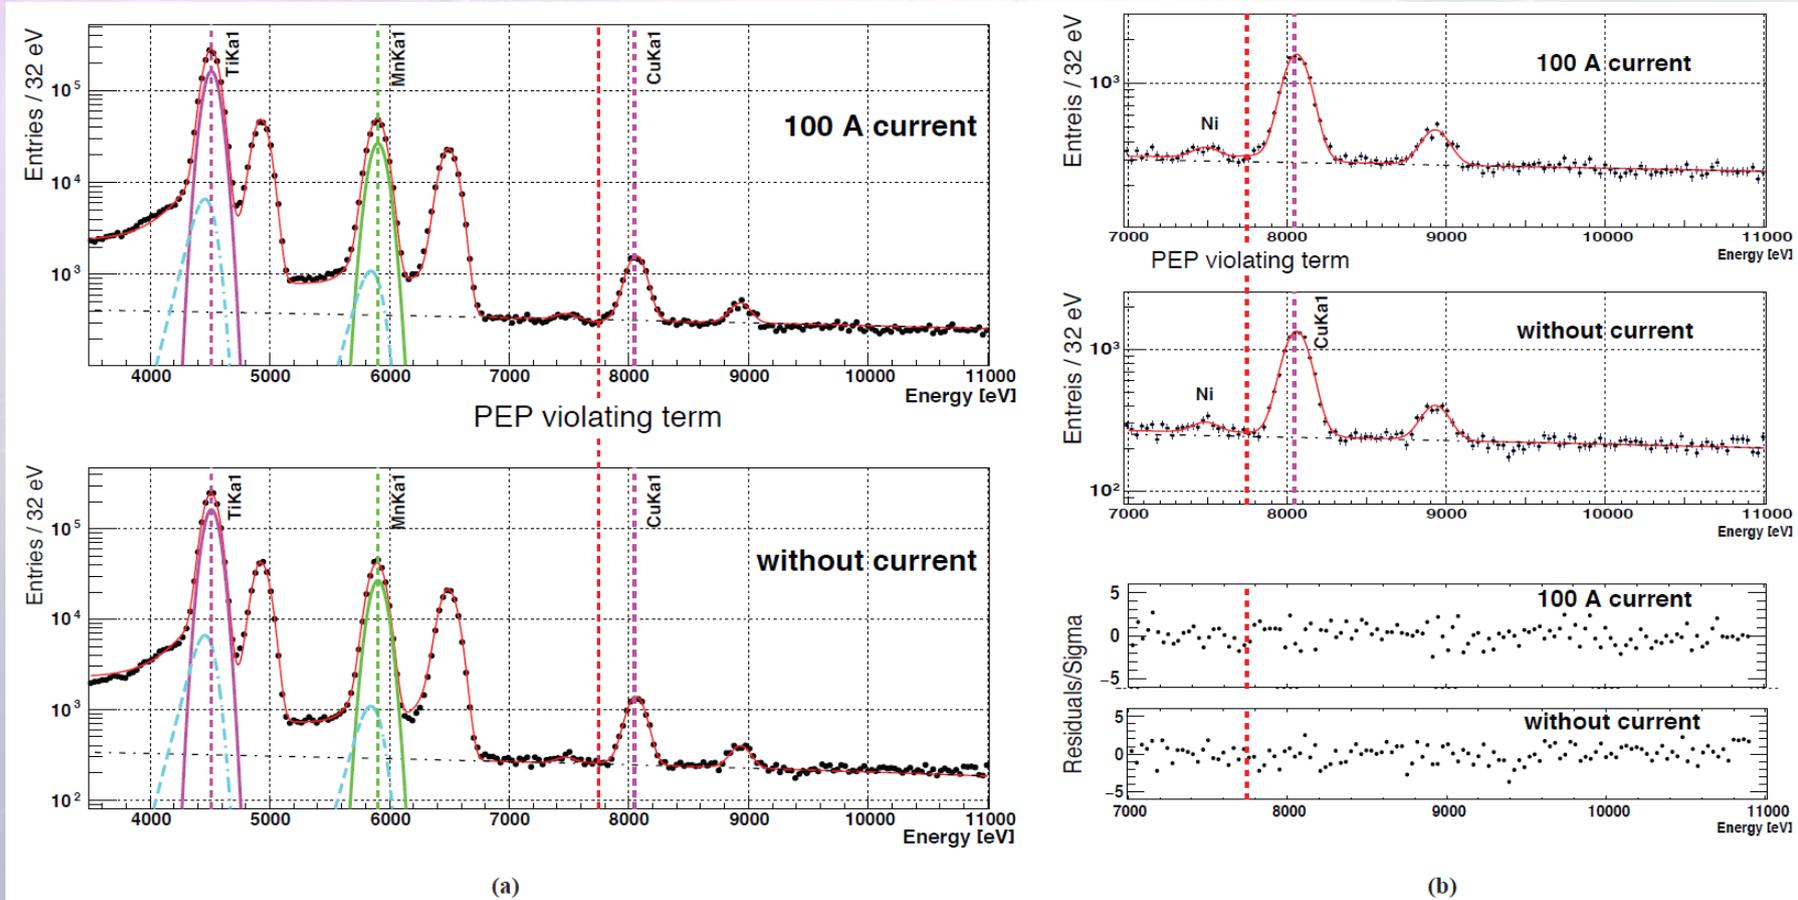

Fig. 8 A global chi-square function was used to fit simultaneously the spectra with and without 100 A current applied to the copper conductor. The energy position for the expected PEP violating events is about 300 eV below the normal copper $K_{\alpha 1}$ transition. The Gaussian function and the tail part of the $K_{\alpha 1}$ components and the continuous background from the fit result are also plotted. (a) : the fit to the wide energy range from 3.5 keV to 11 keV; (b) : the fit and its residual for the 7 keV to 11 keV range where there is no background coming from the calibration source.

Deeper investigation of the electrons diffusion and interaction in a bulk-matter:

On the Importance of Electron Diffusion in a Bulk-Matter
Test of the Pauli Exclusion Principle, *Entropy* 2018, 20(7), 515;
<https://doi.org/10.3390/e20070515>:

Article

On the importance of electron diffusion in a bulk-matter test of the Pauli Exclusion Principle

Edoardo Milotti^{1,*}, Sergio Bartalucci², Sergio Bertolucci³, Massimiliano Bazzi², Mario Bragadireanu^{2,4}, Michael Cargnelli^{2,5}, Alberto Clozza², Catalina Curceanu^{2,4,6}, Luca De Paolis², Jean-Pierre Egger⁷, Carlo Guaraldo², Mihail Iliescu², Matthias Laubenstein⁸, Johann Marton^{2,5}, Marco Miliucci², Andreas Pichler^{2,5}, Dorel Pietreanu^{2,4}, Kristian Piscicchia^{2,6}, Alessandro Scordo², Hexi Shi⁹, Diana Laura Sirghi^{2,4}, Florin Sirghi^{2,4}, Laura Sperandio², Oton Vazquez Doce^{2,10}, Eberhard Widmann⁵ and Johann Zmeskal^{2,5}

The random walks of the electrons as they move from the entrance to the exit of the copper sample is fully described in terms of a diffusion transport model.

PEP violation studies with Pb target & Ge detector

S.R. Elliott et al., Found Phys (2012) 42:1015–1030

relax the definition of *new* (fermion – fermion system interaction)
giving rise to violating Ψ_{sym} .

Exploit free electrons in a conductor (Pb is ideal) → specific electron –
specific atom interactions are so rare $\sim 10^4$ ys each interaction is a new
PEP test

$$\frac{1}{2}\beta^2 < \frac{N_{3\sigma}}{\epsilon_{\text{tot}}} \frac{1}{P_{\text{cpt}} N_{\text{new}}^{\text{free}} N_{\text{int}}^{\text{free}}}$$

where $N_{\text{int}}^{\text{free}}$ and $N_{\text{new}}^{\text{free}}$ are given by

$$N_{\text{int}}^{\text{free}} = \Delta t \frac{v_f}{\mu}$$

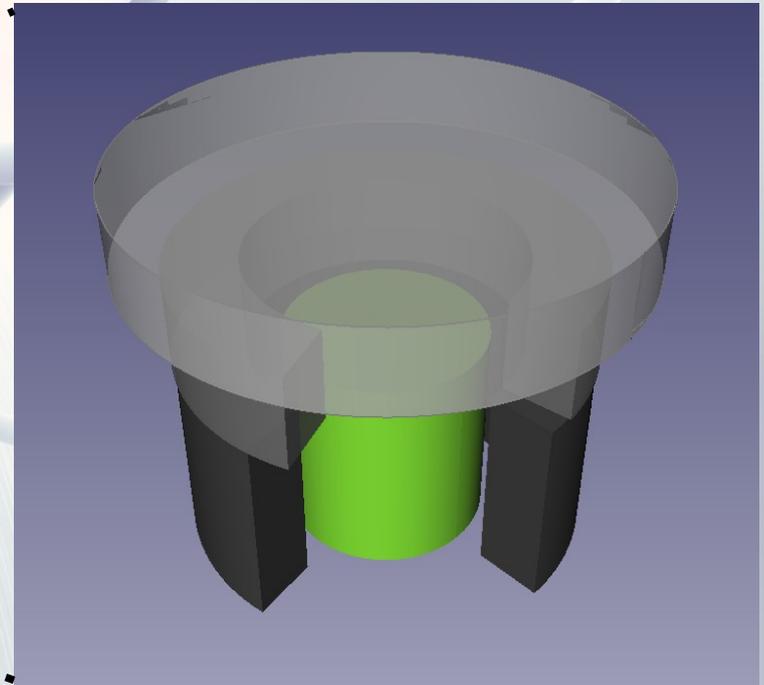

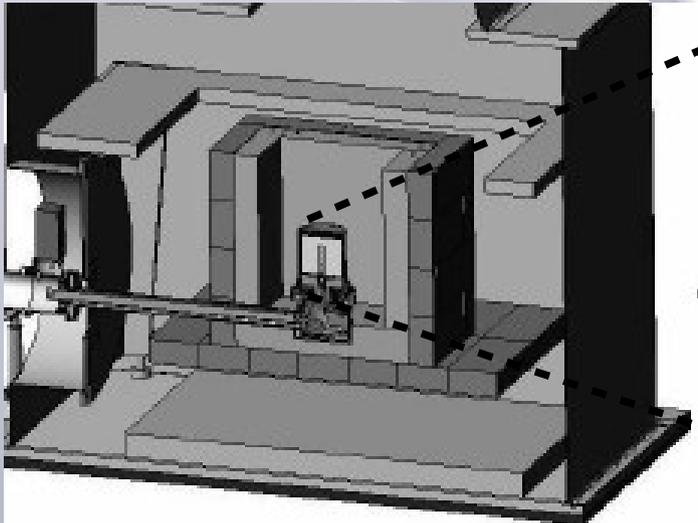

$$N_{\text{new}}^{\text{free}} = N_e V$$

VIP lead with HPGe & LNGS

High purity Ge detector measurement:

- Ge detector surrounded by roman lead target + complex electrolytic Cu + Pb shielding
- ^{10}B -polyethylene plates reduce the neutron flux towards the detector
- shield + cryostat enclosed in air tight steel housing flushed with nitrogen to avoid contact with external air (and thus radon).

VIP lead with HPGe & LNGS

What does rare interactions mean? How many “violating electrons” in the roman lead block could already do violating transitions?

$$P(k) = \frac{(T/N\tau)^k}{k!} \exp(-T/N\tau), \quad \longrightarrow \quad p = P(0) = \exp(-T/N\tau),$$

$$\begin{aligned} p &= \exp(-T/N\tau) + (1 - P_{\text{cpt}}) \frac{(T/N\tau)}{1!} \exp(-T/N\tau) + \dots + (1 - P_{\text{cpt}})^k \frac{(T/N\tau)^k}{k!} \exp(-T/N\tau) + \dots \\ &= \sum_{k=0}^{k=\infty} (1 - P_{\text{cpt}})^k \frac{(-T/N\tau)^k}{k!} \exp(-T/N\tau) \\ &= \exp[-T/(N\tau/P_{\text{cpt}})], \end{aligned}$$

so the PEP violation probability is to be corrected accordingly:

$$\frac{\beta^2}{2} \exp(-T_i P_{\text{cpt}}/N\tau) < \frac{N_X}{\epsilon_{\text{tot}} P_{\text{cpt}} N_{\text{free}} N_{\text{int}}}$$

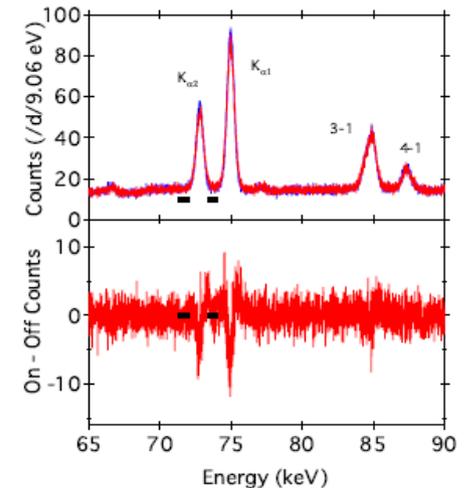

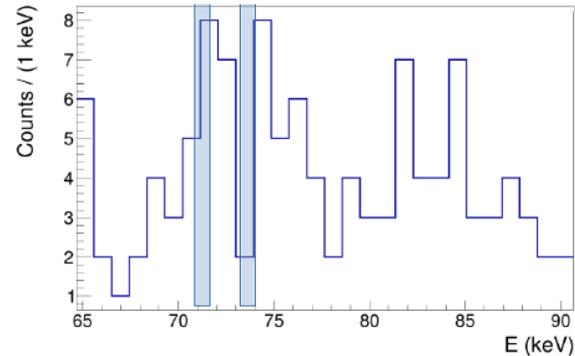

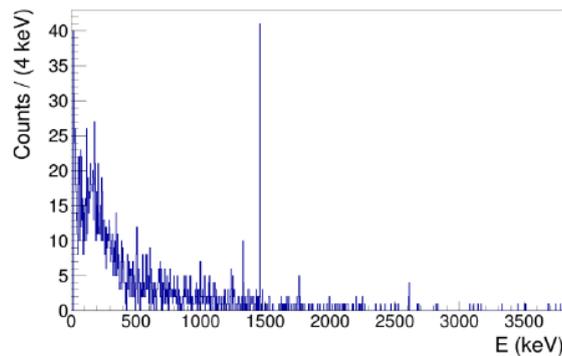

considering our 119 moles of roman Pb samples:

$$\exp(-T_i P_{\text{cpt}}/N\tau) \approx 1.$$

VIP lead with HPGe & LNGS

Extremely low statistics in the two ROI regions compatible with the mean bkg: $b = 4.4$ counts/keV

Transitions in Pb	forb.	allow.
$1s - 2p_{3/2} K_{\alpha 1}$	73713	74961
$1s - 2p_{1/2} K_{\alpha 2}$	71652	72798

S.R. Elliott et al., Found Phys (2012) 42:1015–1030

Figure 1. Total measured X-ray spectrum (left); same spectrum in the region of the K_{α} standard and violating transitions in Pb (right).

The p value (probability of having measured an excess with respect to b in the two ROIs):

$$p = \sum_{j=z_1+1}^{\infty} \frac{b^{z_1}}{z_1!} \exp(-b) \sum_{j=z_2+1}^{\infty} \frac{b^{z_2}}{z_2!} \exp(-b) = \left[1 - \sum_{j=0}^{z_1} \frac{b^{z_1}}{z_1!} \exp(-b) \right] \left[1 - \sum_{j=0}^{z_2} \frac{b^{z_2}}{z_2!} \exp(-b) \right]$$

$p = 0.051$ corresponding to 1.95 standard deviations.

$$\frac{1}{2}\beta^2 < 1.58 \cdot 10^{-40}$$

Factor 16 better than Elliott

Paper in preparation

Thanks

The β parameter

16

$$N_X \geq \frac{1}{2} \beta^2 N_{new} \frac{N_{int}}{10} =$$

$$\frac{\beta^2 (\Sigma I \Delta t) D}{e \mu \rho z \sigma}$$

$$\int_T I(t) dt = 15.44 \cdot 10^6 C$$

$$D = 0.025 m$$

$$m = 3.9 \cdot 10^{-8} m$$

$$\rho = 8.96 \cdot 10^3 kg \cdot m^{-3}$$

$$s = 10 m^2 \cdot kg^{-1}$$

$$z = 1.5 \cdot 10^{-3} m$$

$$N_X \geq \beta^2 (0.90 \cdot 10^{28})$$

$$\beta^2 / 2 \leq 1.7 \cdot 10^{-26} (>95 C.L.)$$

The β parameter

16

Ignatiev & Kuzmin model

creation and destruction operators
connect 3 states

- the vacuum state

$|0\rangle$

- the single occupancy state

$|1\rangle$

- the non-standard double occupancy state

$|2\rangle$

through the following
relations:

$$\begin{array}{ll} a^+|0\rangle|1\rangle & a|0\rangle|0\rangle \\ a^+|1\rangle = \beta |2\rangle a^+|2\rangle = 0 & a|1\rangle \\ & = |0\rangle a|2\rangle = \beta |1\rangle \end{array}$$

The parameter β quantifies the degree of violation in the transition.

$$|1\rangle \rightarrow |2\rangle$$

It is very small and for $\beta \rightarrow 0$ we recover the Fermi - Dirac statistic.

The β parameter

16

this β can be simply related to the q parameter of the quon theory of Greenberg and Mohapatra

$$\frac{1}{2}\beta^2 = \frac{1+q}{2}$$

quon algebra is a sort of weighted average between fermion and boson algebra:

$$\frac{1+q}{2} [a_k, a_l^+]_- + \frac{1-q}{2} [a_k, a_l^+]_+ = \delta_{kl}$$

or also

$$a_k a_l^+ - q a_l^+ a_k = \delta_{kl}$$

Abstract. Searches for non-pauli nuclear processes, i.e. processes normally forbidden by the Pauli Exclusion Principle (PEP) with highly radiopure NaI(Tl) scintillators allow the test of this fundamental principle with high sensitivity. Status and perspectives are briefly addressed.

LNGS Background studies with Monte-Carlo

Electron decoherence time at room temperature

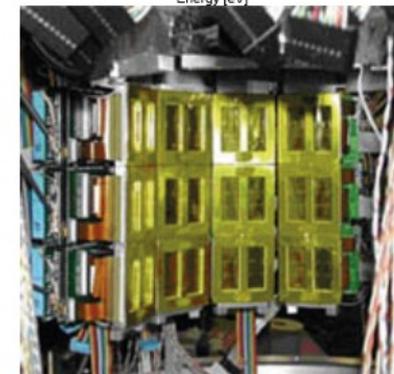

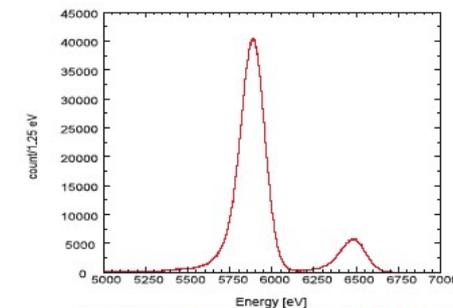

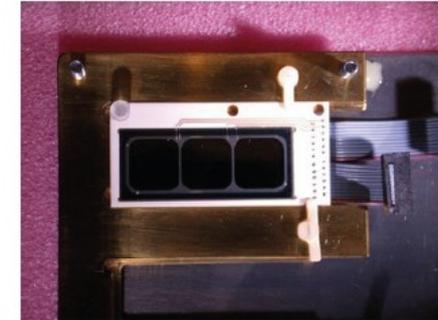

E. Milotti,
Talk, May
29, 2015,
Vienna

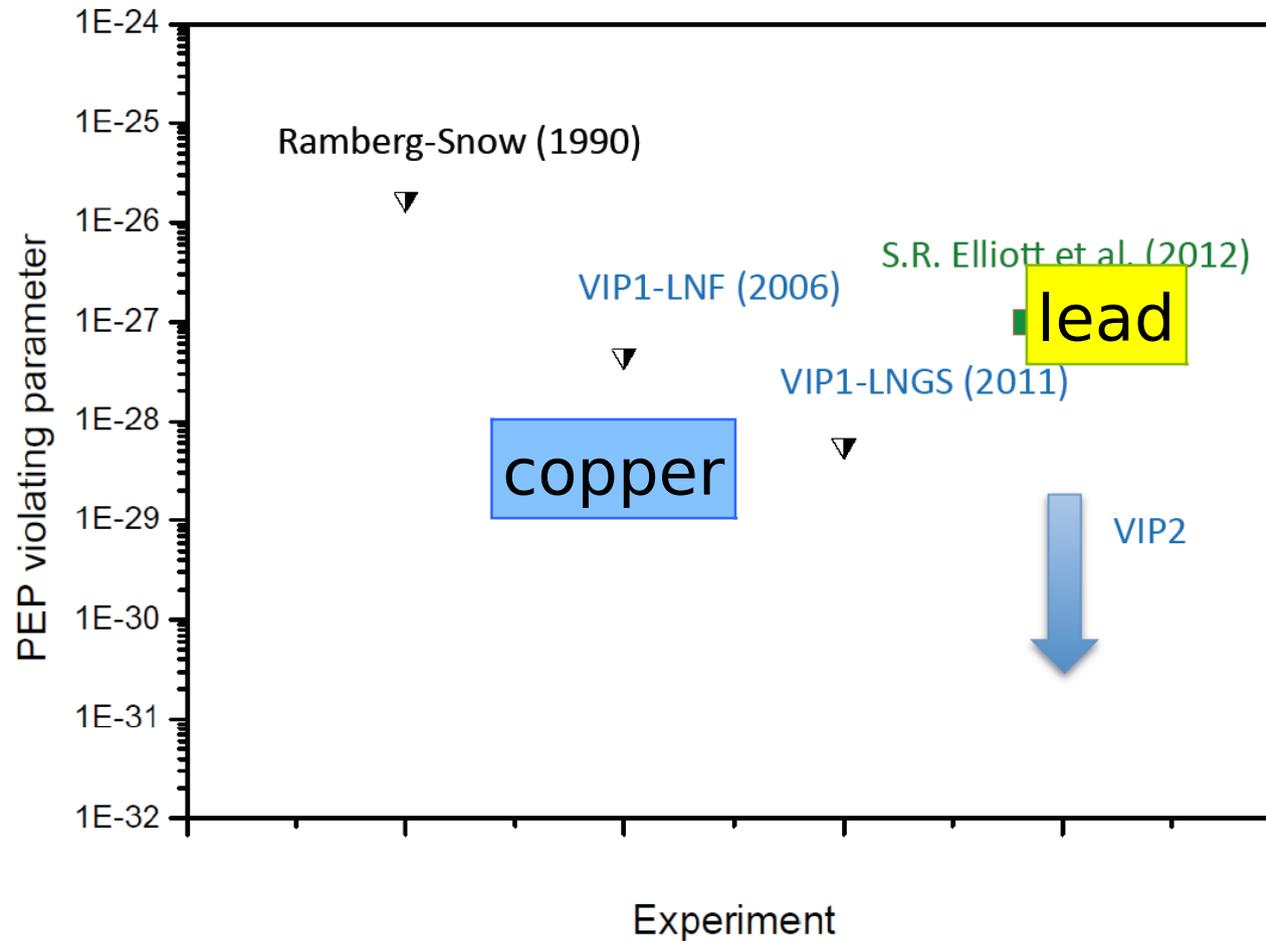

With this decoherence time and the
electron thermal speed we find a
decoherence length of about $10 \mu\text{m}$

The conclusion is that after a time of the order of the *decoherence time* the electron wavefunctions are effectively decoupled and the environment acts on electrons by enforcing an effective locality.

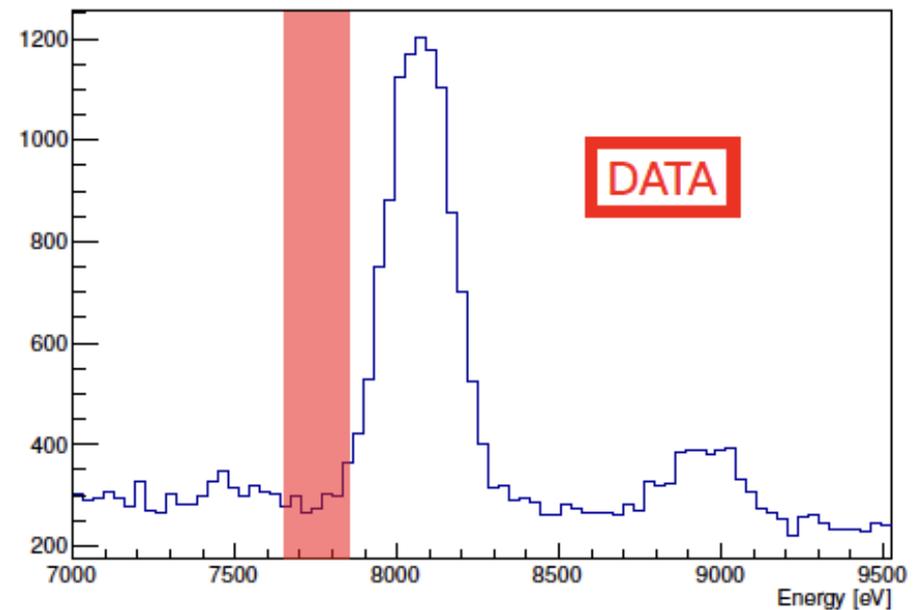

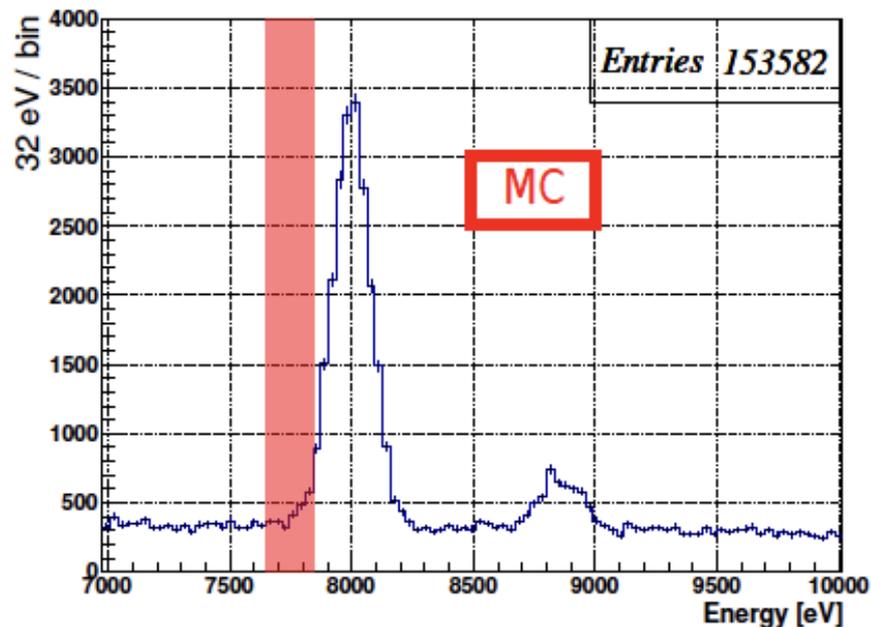

Improved experiment VIP2

- Large (1 cm²) SDDs provide excellent energy resolution (even superior than CCDs at 8keV)
- Timing capability for triggering
- Compact design suitable for gaining larger solid angle
- Successfully used in the detection of kaonic atom x-ray spectroscopy at DAFNE (SIDDHARTA) with large background reduction

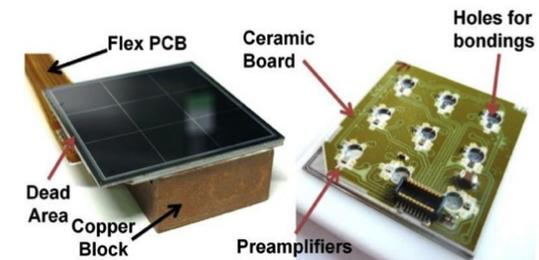

Comparison MC and Data @ LNGS

Monte Carlo simulation of 30 days data
taking and actual
data taken in 30 days

Future Research Plan

- Installation of part of the passive shielding
- New SDD detector system with new copper target
- In 2017 new copper target with new SDDs will be installed
- Optimized shielding with data taking of about 3 years (i.e. approx. 2020)
- Goal after 3 years data taking with and without current
 - ➔ 10^2 improvement of VIP limit

Toward the final result
