B_c meson

Only meson composed of two different heavy quarks

Unique laboratory for two-scale heavy-quark dynamics

B_c meson

-  Only meson composed of two different heavy quarks
-  Unique laboratory for two-scale heavy-quark dynamics
-  Large B_c samples at the LHC (More in future LHC, FCC)
-  Precision studies of leptonic decays becoming feasible

B_c meson

Only meson composed of two different heavy quarks

Unique laboratory for two-scale heavy-quark dynamics

Large B_c samples at the LHC (More in future LHC, FCC)

Precision studies of leptonic decays becoming feasible

- ▶ Purely leptonic decay, $\bar{B}_c \rightarrow l\bar{\nu}$, all hadronic effects encoded in a single decay constant
- ▶ Useful in accurate determinations of $|V_{cb}|$ (next slide)

B_c meson

Only meson composed of two different heavy quarks

Unique laboratory for two-scale heavy-quark dynamics

Large B_c samples at the LHC (More in future LHC, FCC)

Precision studies of leptonic decays becoming feasible

- Purely leptonic decay, $\bar{B}_c \rightarrow l\bar{\nu}$, all hadronic effects encoded in a single decay constant
- Useful in accurate determinations of $|V_{cb}|$ (next slide)

Combines features of heavy-light mesons and heavy quarkonia
A unique heavy-heavy system connecting precision flavour physics and lattice QCD

Why f_{B_c} ?

A precise determination of $|V_{cb}|$ is a central goal of precision flavor physics.

Why f_{B_c} ?

A precise determination of $|V_{cb}|$ is a central goal of precision flavor physics.

- Determined from inclusive and exclusive semileptonic B-meson decays
- A longstanding $2 - 3\sigma$ tension exists between the two determinations

Why f_{B_c} ?

A precise determination of $|V_{cb}|$ is a central goal of precision flavor physics.

- Determined from inclusive and exclusive semileptonic B-meson decays
- A longstanding $2 - 3\sigma$ tension exists between the two determinations
- Exclusive determinations require precise hadronic form factors, making lattice QCD an essential theoretical input.
- A precise f_{B_c} strengthens unitarity bounds, leading to improved $B \rightarrow D^{(*)}$ form factors and a more precise exclusive determination of $|V_{cb}|$

Our Setup

Our Setup

NAVDEEP

Lattice results so far

Why HISQ?

Why HISQ?

NAVDEEP
PAGE 5

Ultrafine lattice spacing ($a \sim 0.0327 \text{ fm}$) allows a fully relativistic treatment of the bottom quark, $am_b = 0.6223$, (also $am_c = 0.137$)

Why HISQ?

NAVDEEP
PAGE 5

Ultrafine lattice spacing ($a \sim 0.0327 \text{ fm}$) allows a fully relativistic treatment of the bottom quark, $am_b = 0.6223$, (also $am_c = 0.137$)

Unlike coarser lattices, which often require specialized heavy-quark actions (e.g., NRQCD or RHQA), our ultrafine lattice allows the bottom quark to be simulated directly with the HISQ action

Why HISQ?

Ultrafine lattice spacing ($a \sim 0.0327 \text{ fm}$) allows a fully relativistic treatment of the bottom quark, $am_b = 0.6223$, (also $am_c = 0.137$)

Unlike coarser lattices, which often require specialized heavy-quark actions (e.g., NRQCD or RHQA), our ultrafine lattice allows the bottom quark to be simulated directly with the HISQ action

Highly Improved Staggered Quark (HISQ) action significantly reduces heavy-quark discretization errors through higher-order improvement.

Ultrafine lattice spacing ($a \sim 0.0327 \text{ fm}$) allows a fully relativistic treatment of the bottom quark, $am_b = 0.6223$, (also $am_c = 0.137$)

Unlike coarser lattices, which often require specialized heavy-quark actions (e.g., NRQCD or RHQA), our ultrafine lattice allows the bottom quark to be simulated directly with the HISQ action

Highly Improved Staggered Quark (HISQ) action significantly reduces heavy-quark discretization errors through higher-order improvement.

Staggered fermions retain four continuum tastes per quark flavor, with meson operators classified by their spin–taste structure

$$\begin{array}{c} \bar{\psi} \Gamma \psi \\ \downarrow \\ \bar{\chi} (\Gamma_S \otimes \Gamma_T) \chi \end{array}$$

Why HISQ?

NAVDEEP
PAGE 5

Ultrafine lattice spacing ($a \sim 0.0327 \text{ fm}$) allows a fully relativistic treatment of the bottom quark, $am_b = 0.6223$, (also $am_c = 0.137$)

Unlike coarser lattices, which often require specialized heavy-quark actions (e.g., NRQCD or RHQA), our ultrafine lattice allows the bottom quark to be simulated directly with the HISQ action

Highly Improved Staggered Quark (HISQ) action significantly reduces heavy-quark discretization errors through higher-order improvement.

Staggered fermions retain four continuum tastes per quark flavor, with meson operators classified by their spin–taste structure

$$\begin{array}{c} \bar{\psi} \Gamma \psi \\ \downarrow \\ \bar{\chi} (\Gamma_S \otimes \Gamma_T) \chi \end{array}$$

- Taste splitting effects suppressed (HISQ), ultrafine lattice spacing taste splitting expected to be small
- No mixed action effects, enables high-precision lattice calculations with controlled discretization errors

Oscillating Correlators

Oscillating Correlators

NAVDEEP
PAGE 6

- ▶ Staggered meson operators couple to both the desired state and its opposite-parity partner

Oscillating Correlators

NAVDEEP
PAGE 6

- ▶ Staggered meson operators couple to both the desired state and its opposite-parity partner
- ▶ Consequently, the two-point correlation function contains oscillating contributions

$$C(t) = \sum_n A_n \left(\exp(-E_n t) + \exp(-E_n(T - t)) \right) - (-1)^t \sum_n B_n \left(\exp(-E_n^o t) + \exp(-E_n^o(T - t)) \right)$$

Oscillating Correlators

NAVDEEP
PAGE 6

- ▶ Staggered meson operators couple to both the desired state and its opposite-parity partner
- ▶ Consequently, the two-point correlation function contains oscillating contributions

$$C(t) = \sum_n A_n \left(\exp(-E_n t) + \exp(-E_n(T - t)) \right) - (-1)^t \sum_n B_n \left(\exp(-E_n^o t) + \exp(-E_n^o(T - t)) \right)$$

Oscillating contributions produce
an even-odd time-slice pattern

Oscillating Correlators

- ▶ Staggered meson operators couple to both the desired state and its opposite-parity partner
- ▶ Consequently, the two-point correlation function contains oscillating contributions

$$C(t) = \sum_n A_n \left(\exp(-E_n t) + \exp(-E_n(T - t)) \right) - (-1)^t \sum_n B_n \left(\exp(-E_n^o t) + \exp(-E_n^o(T - t)) \right)$$

Oscillating contributions produce
an even-odd time-slice pattern

A three-point smoothing is applied
to reduce these oscillations

$$C(t) = \sqrt{C(t) \sqrt{C(t-1) C(t+1)}}$$

B_c signal

NAVDEEP
PAGE 7

B_c signal

Effective mass constructed from smoothed correlators and shown without bootstrap/jackknife uncertainties to highlight the signal quality

B_c signal

Effective mass constructed from smoothed correlators and shown without bootstrap/jackknife uncertainties to highlight the signal quality

$$f_{ps} = \left(m_{q_1} + m_{q_2} \right) \sqrt{\frac{2A}{E^3}}$$

Oscillating ansatz becomes increasingly noisy at large Euclidean times, single exponential fits to smooth data

B_c signal

Effective mass constructed from smoothed correlators and shown without bootstrap/jackknife uncertainties to highlight the signal quality

$$f_{ps} = \left(m_{q_1} + m_{q_2} \right) \sqrt{\frac{2A}{E^3}}$$

Oscillating ansatz becomes increasingly noisy at large Euclidean times, single exponential fits to smooth data

A naive check to verify that no information is lost through smoothing

B_c^* signal

NAVDEEP

Extracting More ...

So far, we have focused on single-exponential fits to extract the ground-state properties

However, correlation functions contain richer spectral information

Can be accessed using advanced spectral extraction techniques

Using these methods, we

get a validation of our ground states numbers

can validate the impact of excited-state contamination

get faster convergence and improved numerical stability

- Lanczos, **Wagman**

TGEVP Setup

Truncated Krylov Subspace $\mathcal{K}_m$

$$\mathcal{K}_m \equiv \{ |\chi\rangle, \hat{\mathcal{T}} |\chi\rangle, \hat{\mathcal{T}}^2 |\chi\rangle, \dots, \hat{\mathcal{T}}^m |\chi\rangle \},$$

for $2m - 1 \leq n_T$

Transfer Matrix T_{ij}^m

$$T_{ij}^m = \langle v_i | \hat{\mathcal{T}} | v_j \rangle = C(i + j + 1) / \sqrt{C(2i) \times C(2j)}$$

One time step ahead, encodes transfer matrix action on Krylov basis

Overlap Matrix V_{ij}^m

$$V_{ij}^m = \langle v_i | v_j \rangle = C(i + j) / \sqrt{C(2i) \times C(2j)}$$

Encodes overlaps between the Krylov basis states using correlator values

Solve the Generalised Eigenvalue Problem

$$T^m x_n^m = \lambda_n^m V^m x_n^m \quad E_n^m = -\log \lambda_n^m$$

T^m and V^m are positive definite $\rightarrow \lambda_n$'s are real and positive $0 < \lambda_n^m \leq 1$

TGEVP Results

NAVDEEP
PAGE 12

$$C(t) = \sum_n A_n \left(\exp(-E_n t) + \exp(-E_n(T - t)) \right) - (-1)^t \sum_n B_n \left(\exp(-E_n^o t) + \exp(-E_n^o(T - t)) \right)$$

Ansatz incorporates four non-oscillating and three oscillating states

TGEVP Results

$$C(t) = \sum_n A_n \left(\exp(-E_n t) + \exp(-E_n(T - t)) \right) - (-1)^t \sum_n B_n \left(\exp(-E_n^o t) + \exp(-E_n^o(T - t)) \right)$$

Ansatz incorporates four non-oscillating and three oscillating states

Ground-state information obtained from the late-time region is used to constrain fits at early times, where excited-state contributions are significant

► Excited-state decay constants:
work in progress (more statistics
and systematics underway)

- Excited-state spectrum is well established in lattice QCD
- Single-operator TGEVP provides a complementary cross-check of excited-state contamination and extraction

Summary

Summary

NAVDEEP
PAGE 15

- ☑ Performed a high-precision lattice QCD calculation of the B_c meson family decay constants using fully relativistic $N_f = 2 + 1 + 1$ HISQ ensembles

Summary

NAVDEEP
PAGE 15

☒ Performed a high-precision lattice QCD calculation of the B_c meson family decay constants using fully relativistic $N_f = 2 + 1 + 1$ HISQ ensembles

☒ Obtained preliminary results:

$$f_{B_c} = 449.76(97)(?) \text{ MeV}, f_{B_c^*}/Z = 438.82(161)(?) \text{ MeV}, f_{B_c^*}^T/Z = 394.02(150)(?) \text{ MeV}$$

Summary

- ☑ Performed a high-precision lattice QCD calculation of the B_c meson family decay constants using fully relativistic $N_f = 2 + 1 + 1$ HISQ ensembles
- ☑ Obtained preliminary results:
$$f_{B_c} = 449.76(97)(?) \text{ MeV}, f_{B_c^*}/Z = 438.82(161)(?) \text{ MeV}, f_{B_c^*}^T/Z = 394.02(150)(?) \text{ MeV}$$
- ☑ Implemented TGEVP to strengthen extraction of ground-state and enable a systematic study of excited-state properties

Summary

- ☒ Performed a high-precision lattice QCD calculation of the B_c meson family decay constants using fully relativistic $N_f = 2 + 1 + 1$ HISQ ensembles
- ☒ Obtained preliminary results:
$$f_{B_c} = 449.76(97)(?) \text{ MeV}, f_{B_c^*}/Z = 438.82(161)(?) \text{ MeV}, f_{B_c^*}^T/Z = 394.02(150)(?) \text{ MeV}$$
- ☒ Implemented TGEVP to strengthen extraction of ground-state and enable a systematic study of excited-state properties
- ☐ To increase statistics by analyzing more configurations; investigate renormalisation factors
- ☐ A complete systematic error budget for ground- and excited-state B_c spectroscopy
