Quantum Technologies for Neutrino Mass

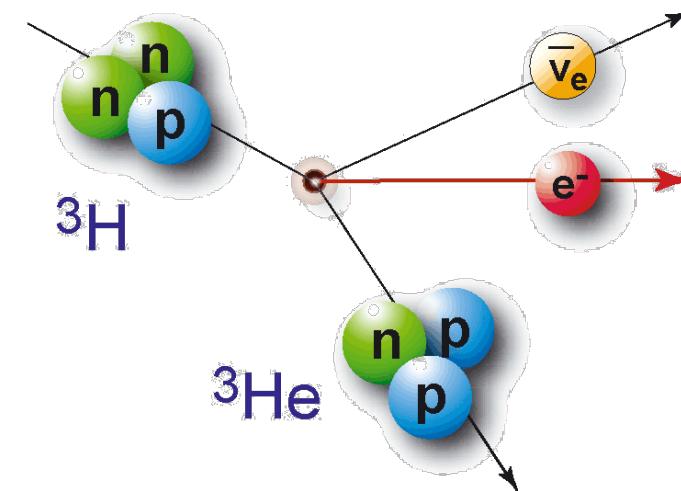

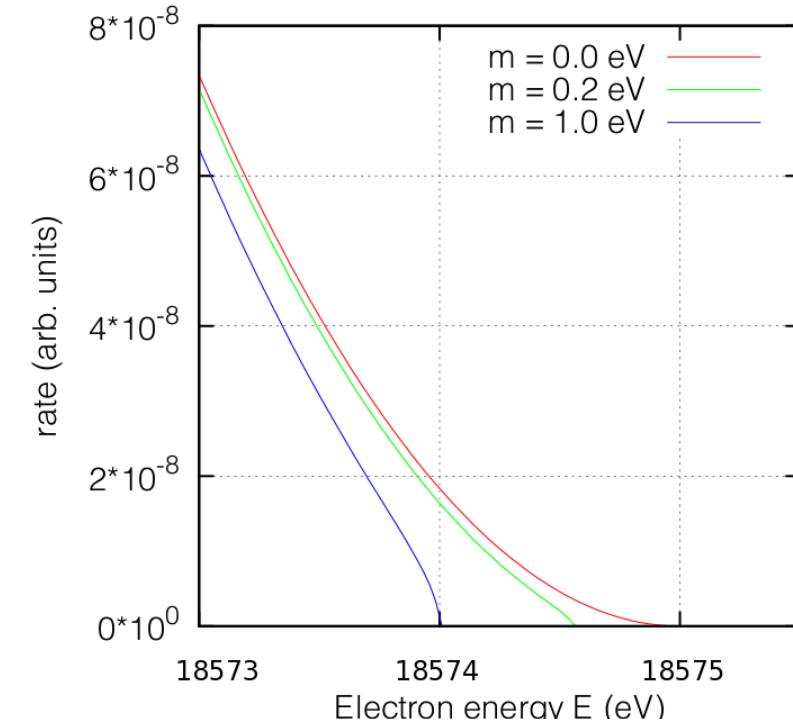

Plan

- QTNM Overview (this lecture): Ruben Saakyan and Seb Jones
 - Neutrino Physics and QTNm
 - Cyclotron Radiation Emission Spectroscopy
- Quantum Electronics (Wed 11-Jan 9:30): Stafford Withington and Songyuan Zhao
 - Quantum Electronics
 - Parametric Amplifiers
- QTNm Tutorial (Wed 11-Jan 11:30): Ruben, Seb, Stafford, Songyan
 - Q&A: Everything you wanted to know... but were afraid to ask
 - Example questions in lectures

Outline of QTNP Overview

- The question of neutrino mass
- ${}^3\text{H}$ β -decay. State of the art
- "Never measure anything but frequency..."
- QTNP Project
- Outlook

The Neutrino History

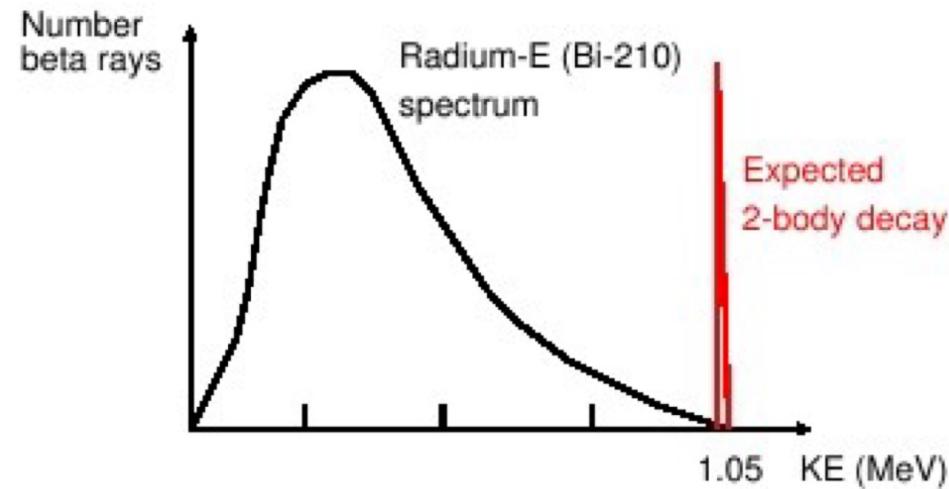

- Existence first postulated by W. Pauli in 1930 to explain the continuous shape of β -spectrum and “save” energy conservation
- Direct detection from a nuclear reactor source by Cowan & Reines in 1956
- Three flavours discovered. “Massless” according to initial Standard Model formulation

Physikalisches Institut
der Eidg. Technischen Hochschule
Zürich, 4. Dez. 1930
Gloriastrasse

Liebe Radioaktive Damen und Herren,

Wie der Ueberbringer dieser Zeilen, den ich huldvollst
anzuhören bitte, Ihnen des näheren auseinandersetzen wird, bin ich
angesezt der "falschen" Statistik der N- und Li-6 Kerne, sowie
des kontinuierlichen beta-Spektrums auf einen verzweifelten Ausweg
verfallen um den "Wechselgatz" (1) der Statistik und den Energiesatz
zu retten. Nämlich die Möglichkeit, es könnten elektrisch neutrale
Teilchen, die ich Neutronen nennen will, in den Kernen existieren,
welche den Spin 1/2 haben und das Ausschliessungsprinzip befolgen und
sich von Lichtquanten zusserdem noch dadurch unterscheiden, dass sie
nicht mit Lichtgeschwindigkeit laufen. Die Masse der Neutronen
müsste von derselben Grossenordnung wie die Elektronenmasse sein und
jedenfalls nicht grösser als 0,01 Protonenmasse... Das kontinuierliche
beta-Spektrum wäre dann verständlich unter der Annahme, dass beim
beta-Zerfall mit dem elektron jeweils noch ein Neutron emittiert
wird, derart, dass die Summe der Energien von Neutron und elektron
konstant ist.

"At the present stage of atomic theory we have no arguments for upholding the concept of energy balance in the case of β -ray disintegrations."

Standard Model of Elementary Particles

Most abundant particle of matter in the Universe (330 cm^{-3}) that we still do not know much about!

Mass assumed to be zero in SM (for good reasons which was now experimentally shown not to be true (neutrino oscillations))

Neutrino Oscillations

- Neutrinos interact as flavour eigenstates but propagate as mass eigenstates

- Mixing between neutrino mass and flavour eigenstates is governed by a unitary matrix
- The end observable effect is neutrino oscillations between flavours

simplified two-neutrino case

$$P(\nu_e \rightarrow \nu_\mu) = \sin^2 2\theta \sin^2 \left(\frac{\Delta m_{21}^2 L}{4E} \right)$$

with

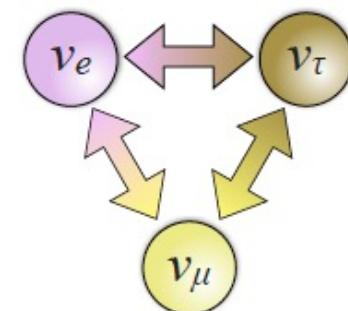

$$\Delta m_{21}^2 = m_2^2 - m_1^2$$

Neutrino Oscillations

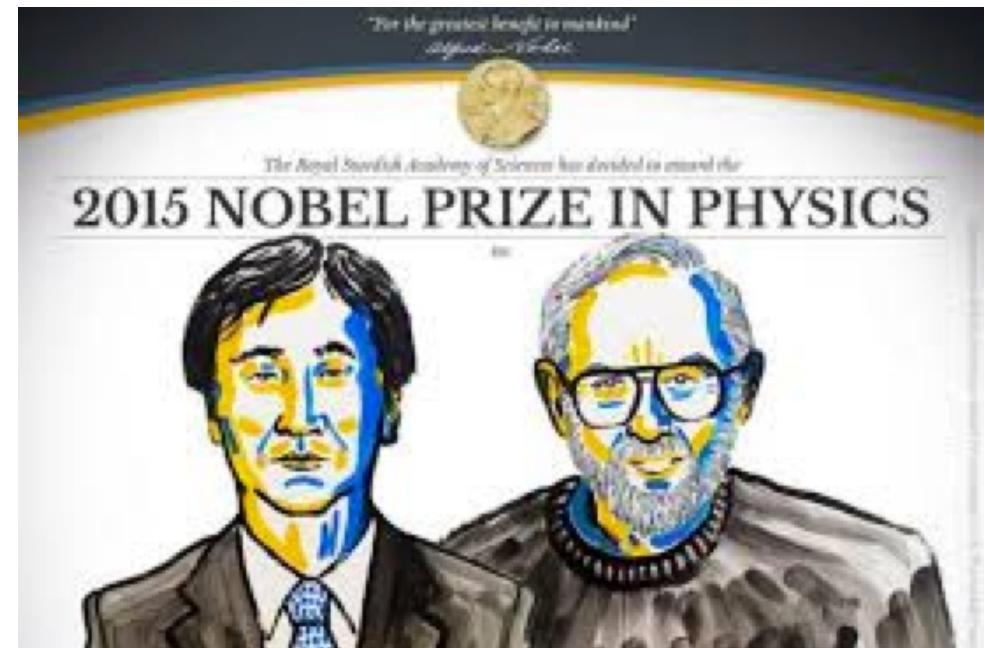

Non-zero neutrino mass

$$U = \begin{pmatrix} U_{e1} & U_{e2} & U_{e3} \\ U_{\mu 1} & U_{\mu 2} & U_{\mu 3} \\ U_{\tau 1} & U_{\tau 2} & U_{\tau 3} \end{pmatrix}$$

Neutrino Oscillations

- **Evidence** from atmospheric, solar, reactor and accelerator experiments
- 2015 Nobel Prize in Physics to T. Kajita and A. McDonald
- Tremendous progress in past decade, **precise measurements** of three mixing angles and two Δm^2
- **Ambitious** multi-billion-\$ programme over next decades (HyperK, DUNE)
- However, neutrino oscillations only give mass (squared) differences between neutrino mass eigenstates, **no information on absolute neutrino mass**

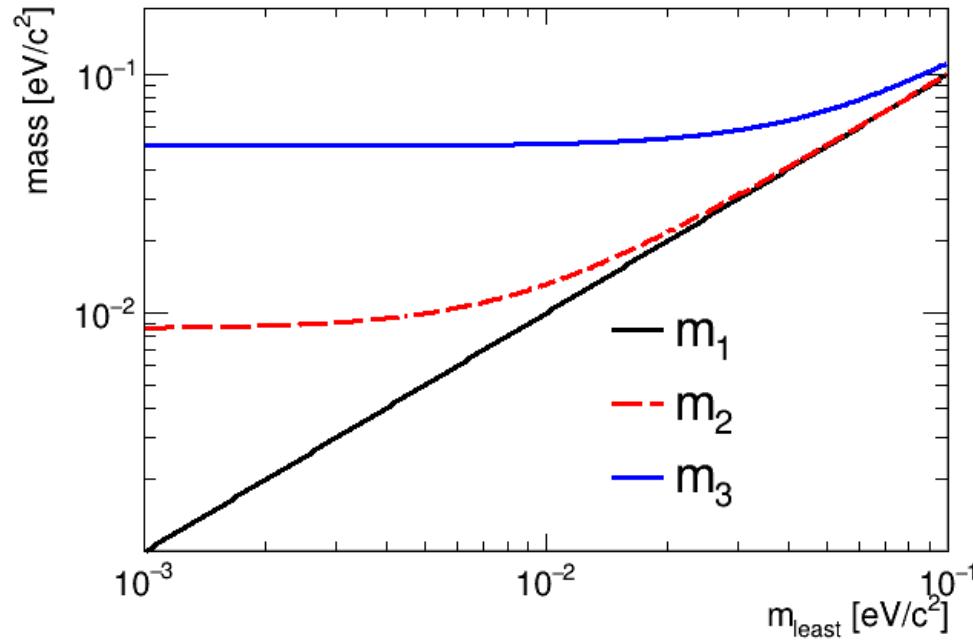

Constraints from Neutrino Oscillations

m_3

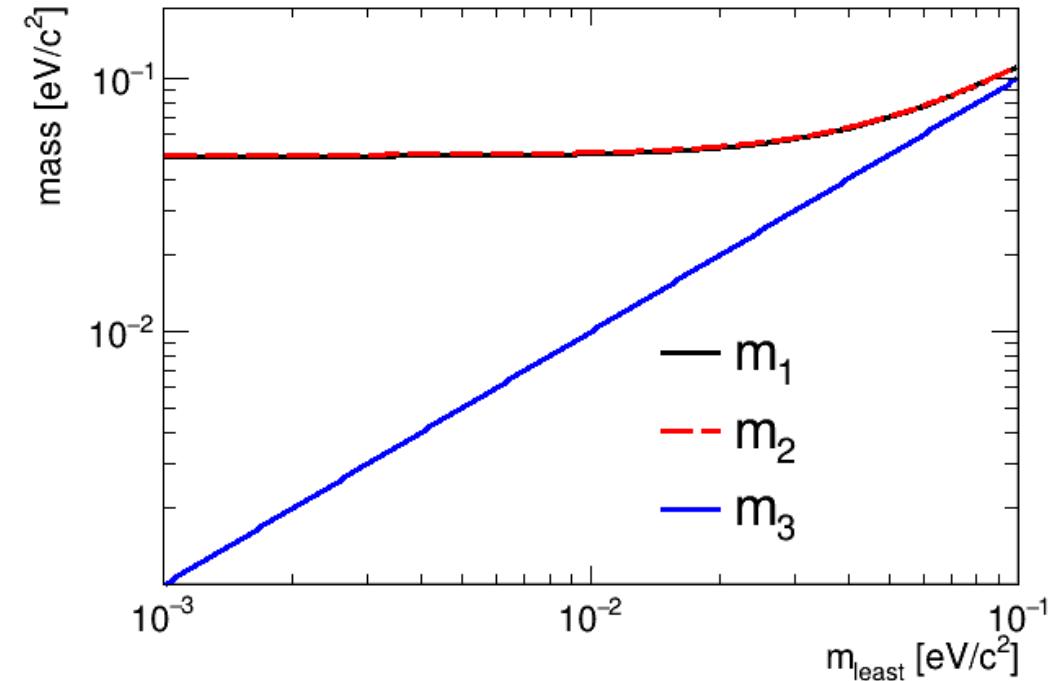

m_2
 m_1

Normal

Normal hierarchy

Inverted hierarchy

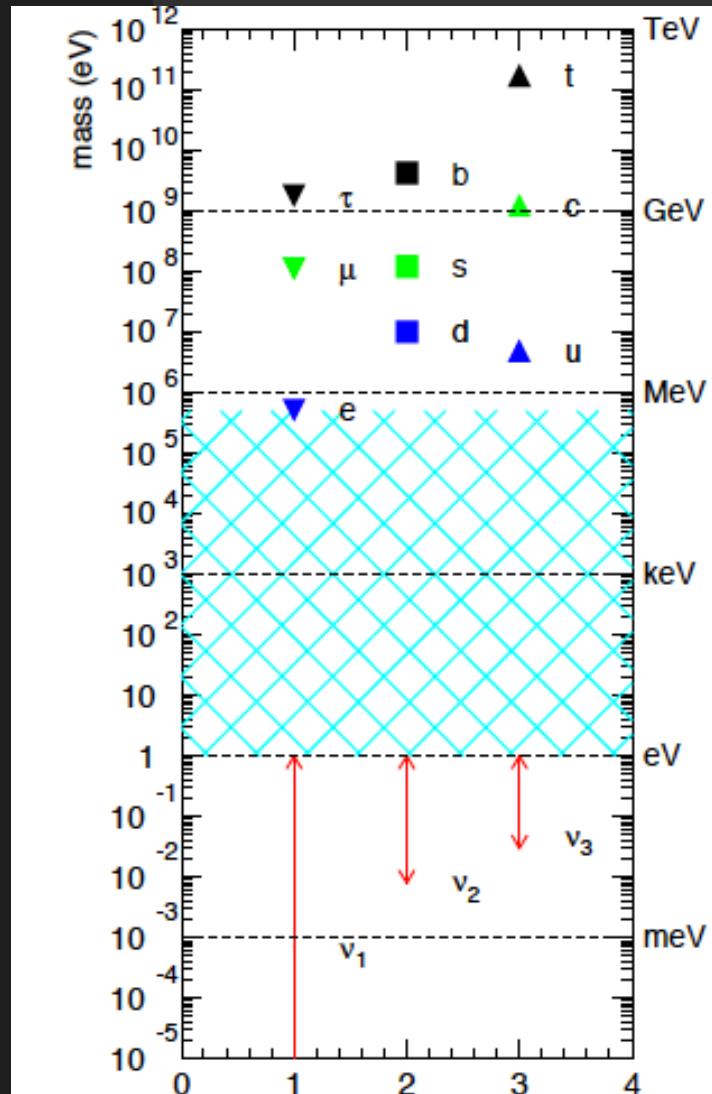

m_2
 m_1

m_3

Inverted

Absolute mass depends on the neutrino mass ordering

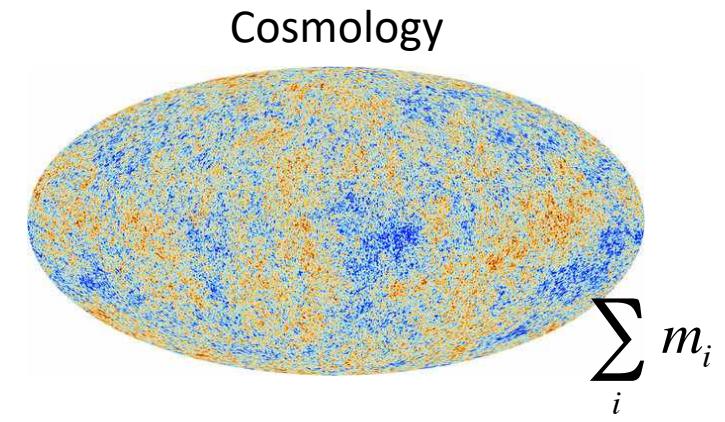

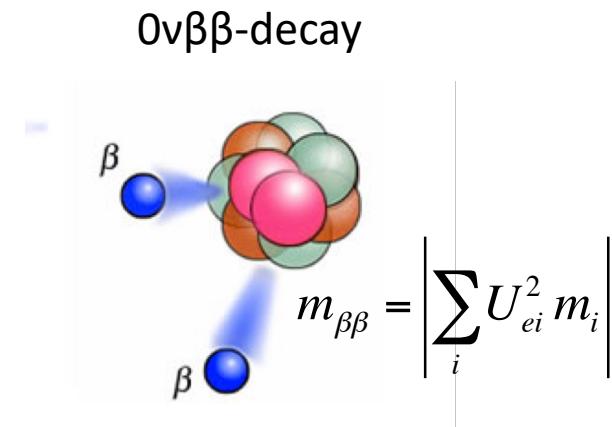

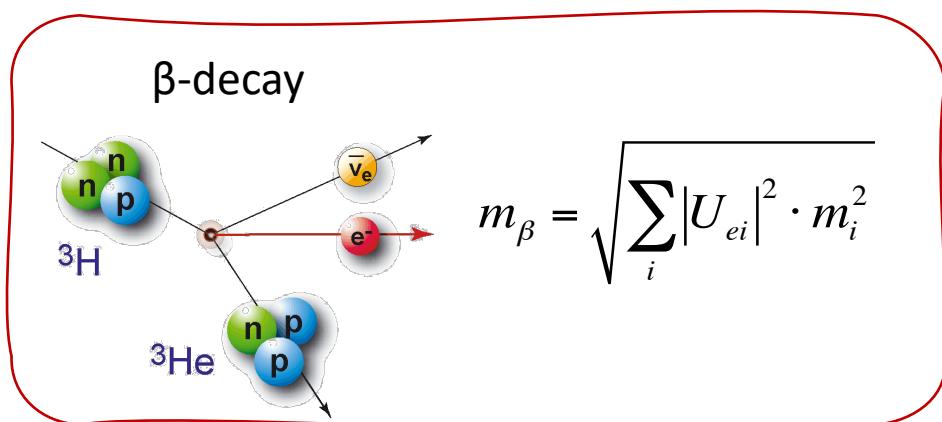

Neutrino mass

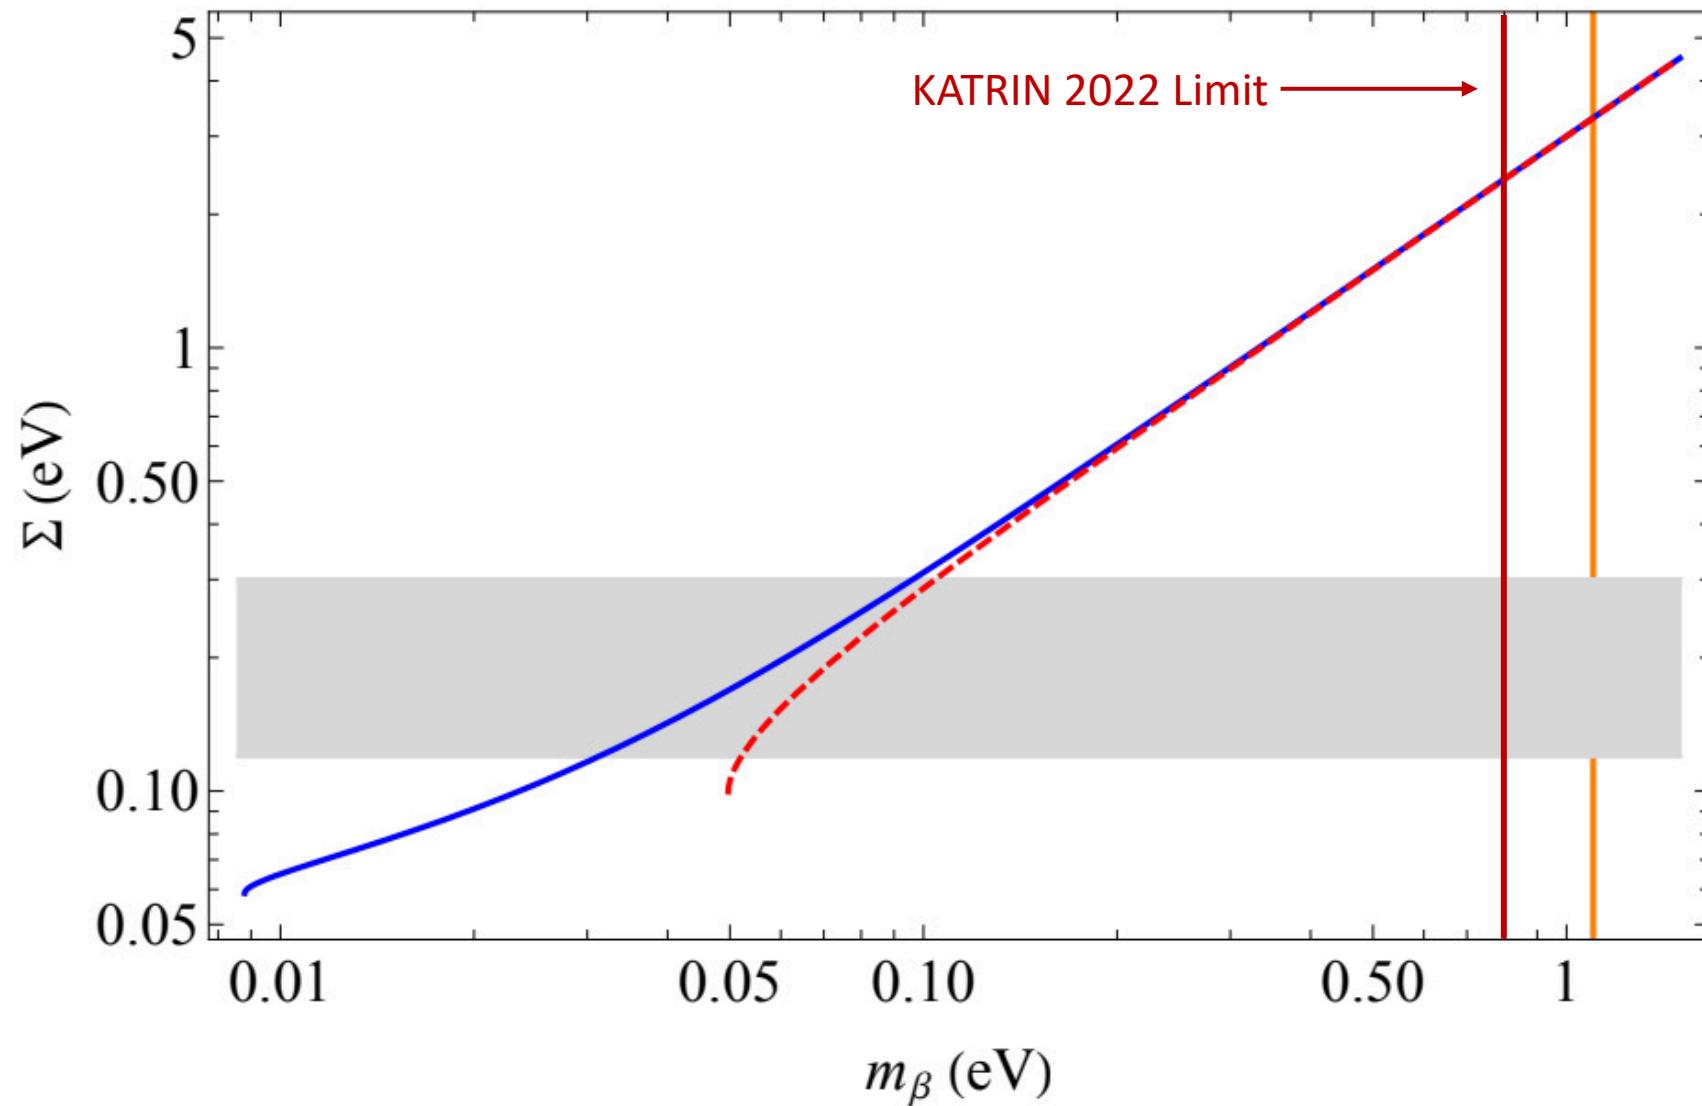

- Only solid particle physics evidence for Physics beyond Standard Model
- Smallness of mass suggests new mass generation mechanism (not “straight” Higgs)
- Connected to new physics
 - Matter-antimatter asymmetry (CP-violation)
 - Lepton Number Violation
 - Sterile-neutrino

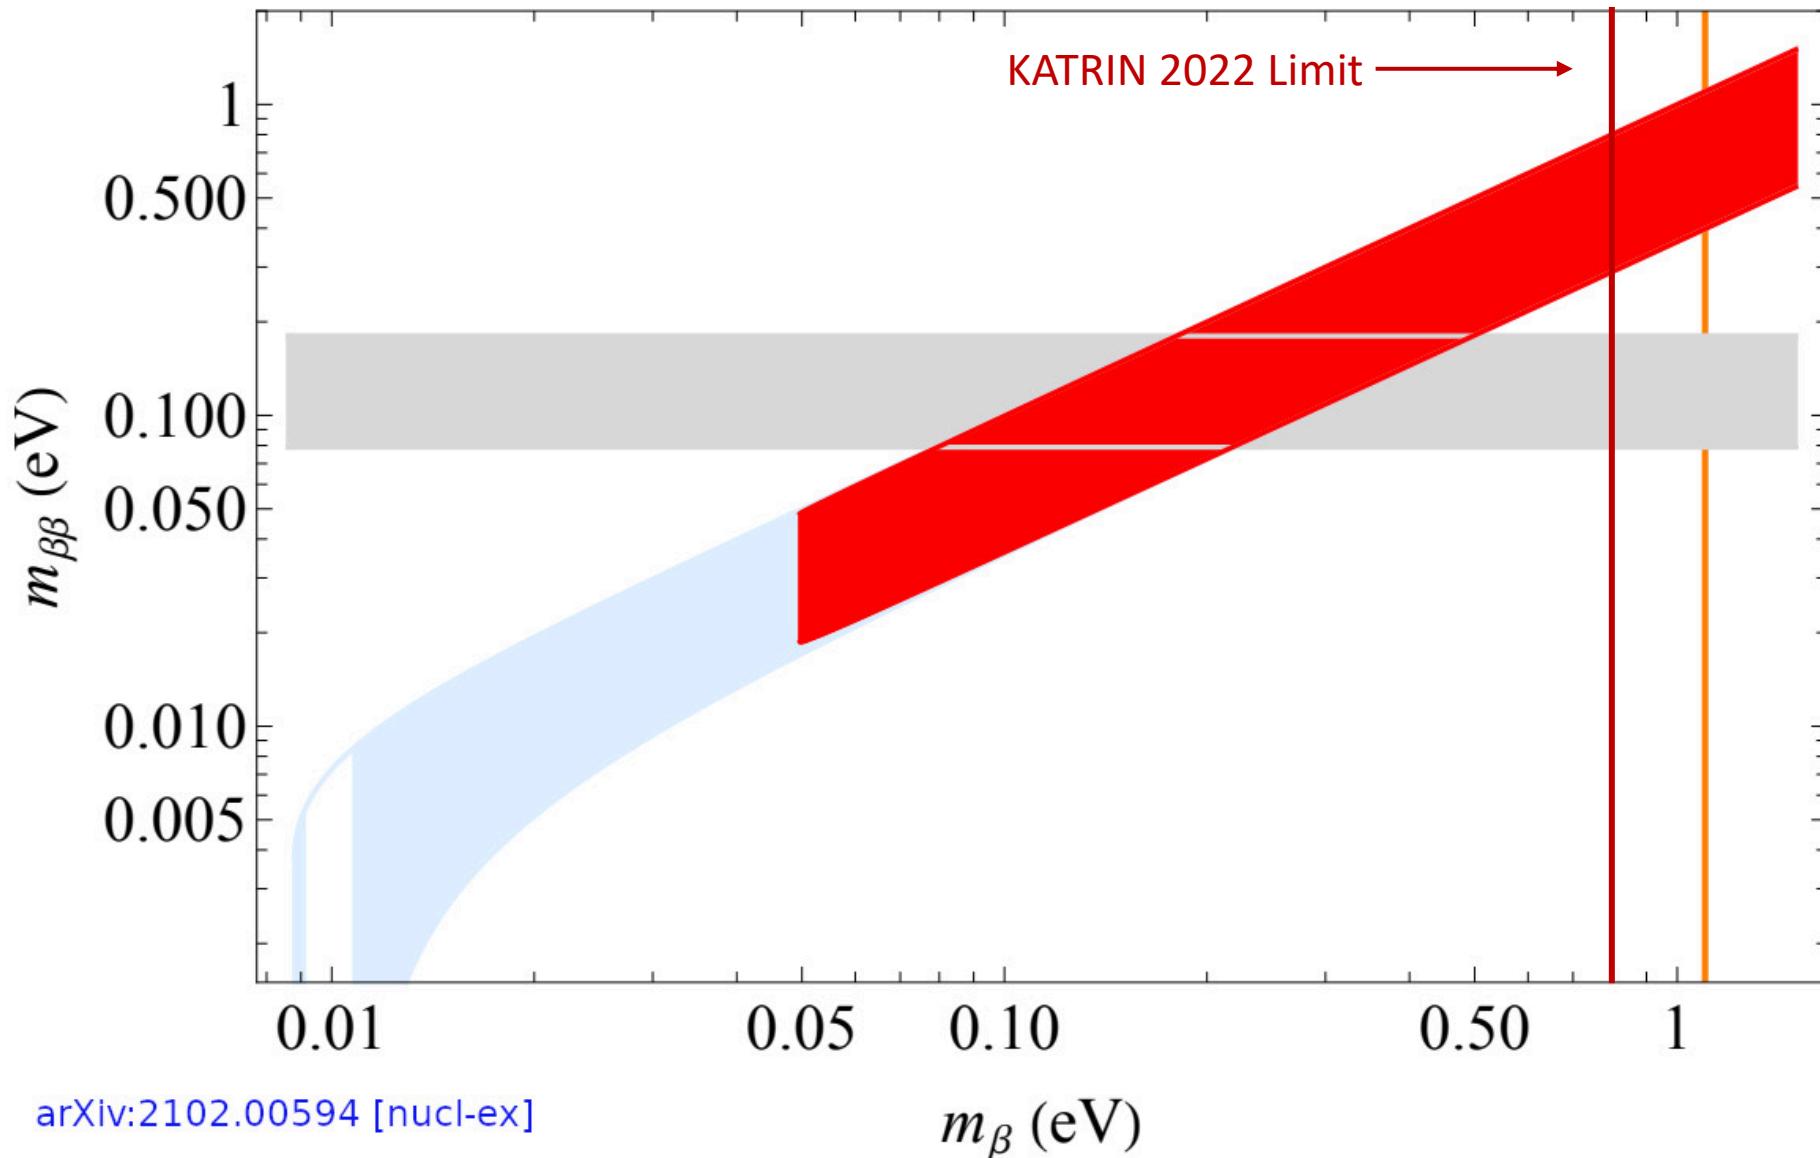

Absolute neutrino mass is a key unanswered question that connects it all.

How to access Absolute Neutrino Mass

- Measurement **all three** neutrino mass parameters allows **Majorana CP-violating phases** to be constrained (otherwise inaccessible!) → key for understanding **matter-antimatter asymmetry** of Universe
- Measuring m_β in **β -decay** constrains $m_{\beta\beta}$ (**0v $\beta\beta$**) and Σ (**Cosmology**)
 - next two slides

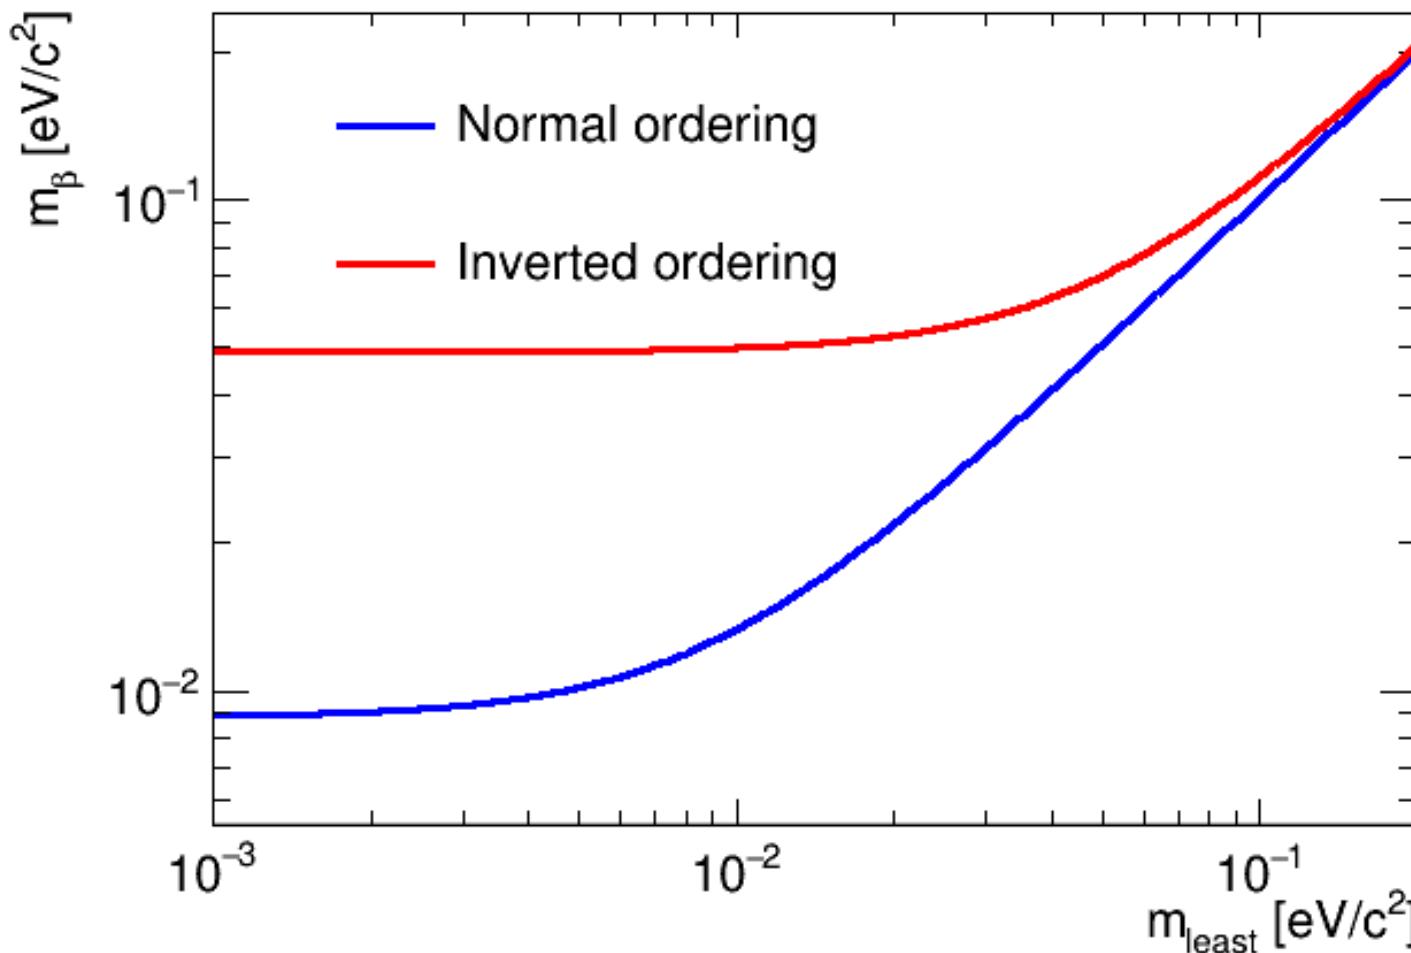

arXiv:2102.00594 [nucl-ex]

m_β (eV)

To summarise:

- m_β is sensitive to neutrino mass ordering
- Cannot be smaller than 9 meV (worst case scenario)

$$m_\beta^2 = m_1^2 + |U_{e2}|^2 \Delta m_{21}^2 + |U_{e3}|^2 \Delta m_{31}^2$$

$\Delta m_{31}^2 > 0$: Normal Ordering

$\Delta m_{31}^2 < 0$: Inverted Ordering

Model Independent Neutrino Mass Measurement

E. Fermi, Z. Phys. 88 (1934) 161

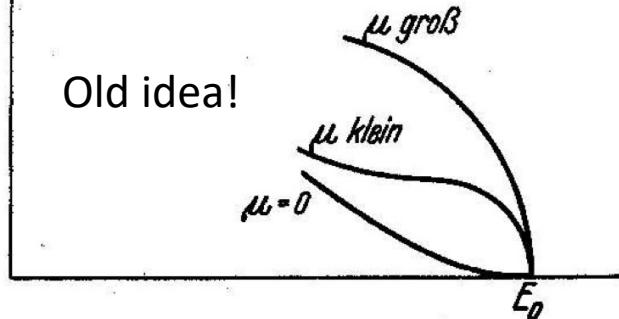

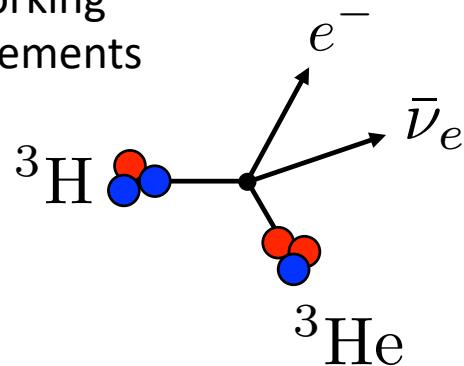

Fig. 1.

Tritium β -decay is a “working horse” of these measurements

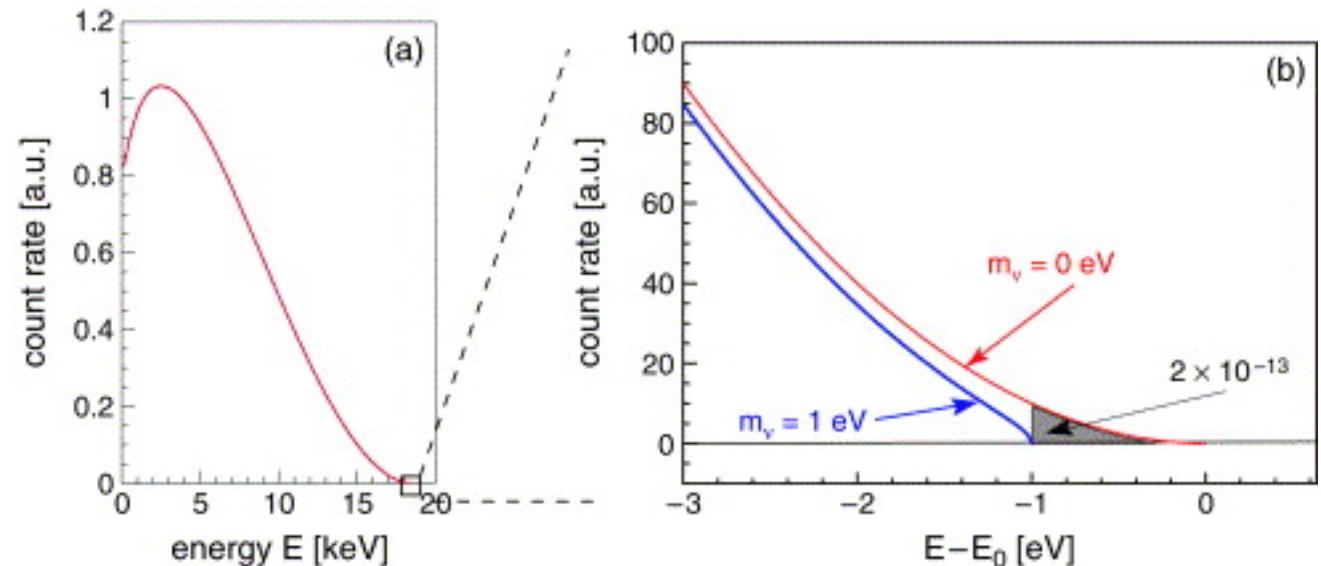

But other isotopes possible for calorimetric measurements

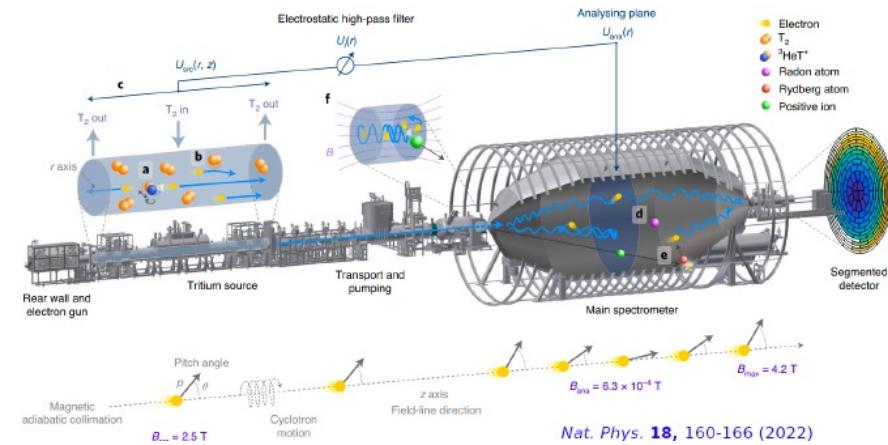

Energy conservation is only assumption!

$$\frac{d\Gamma_i}{dE} = C p(E+m_e)(E_0-E)\sqrt{(E_0-E)^2 - m_\nu^2} F(E) \theta(E_0-E-m_\nu)$$

$$m_\beta = \sqrt{U_{e1}^2 m_1^2 + U_{e2}^2 m_2^2 + U_{e3}^2 m_3^2}$$

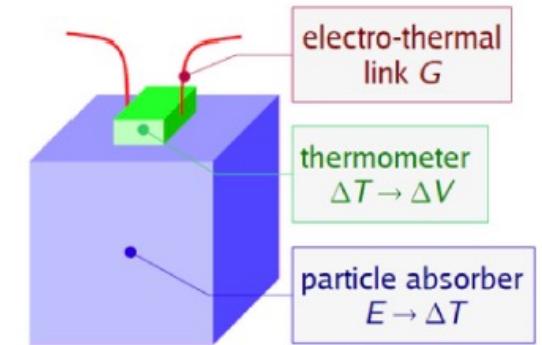

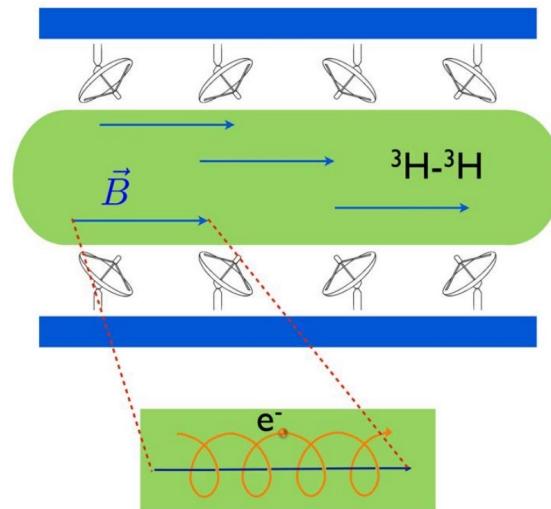

Three methods of m_β measurement

Electrostatic filter
(retarding potential)

Cyclotron Radiation
Emission Spectroscopy
(CRES)

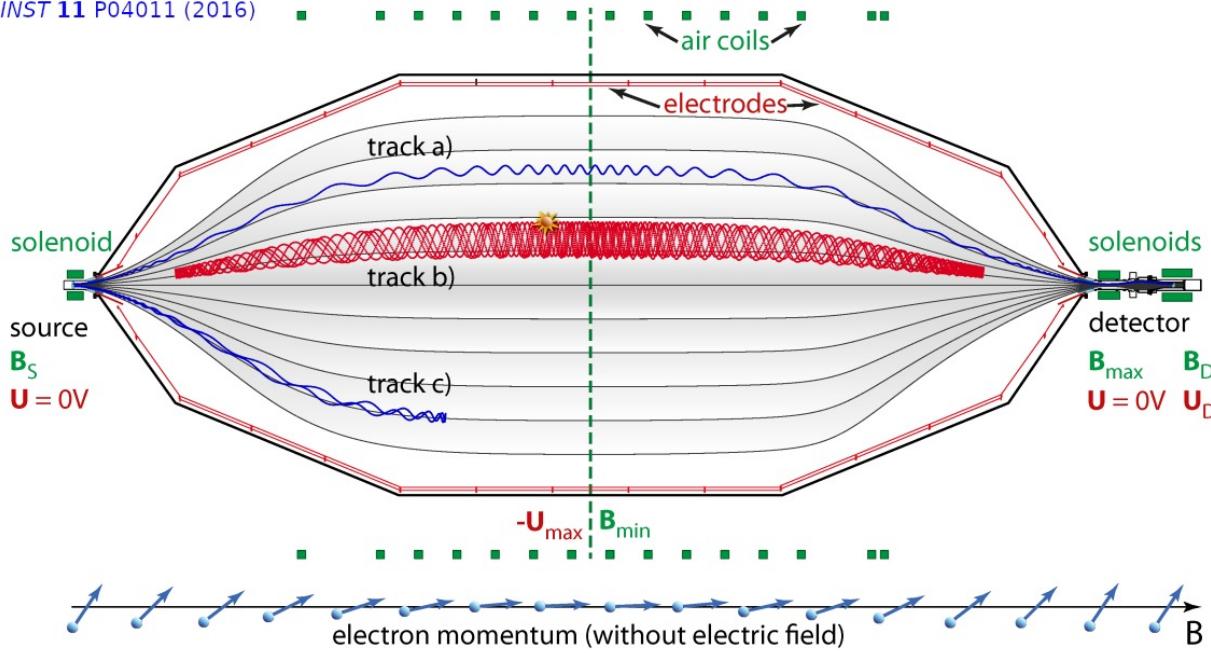

Calorimetry

State-of-the-art: KATRIN Experiment

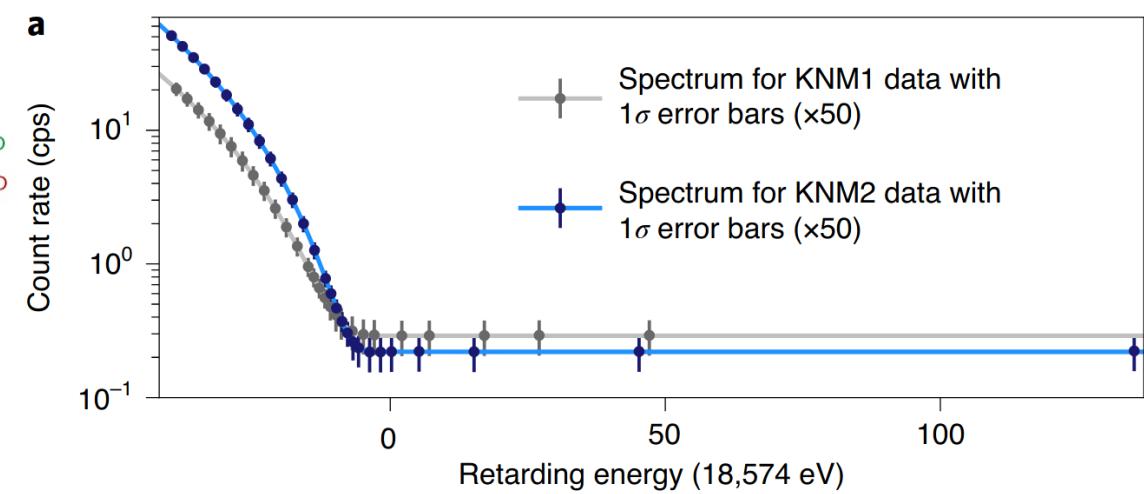

Magnetic Adiabatic Collimation + Electrostatic Filter (MACE)

JINST 11 P04011 (2016)

Source activity 10^{11} Bq
 T_2 throughput ~ 40 g/day
 Operation 24/7, 60 days/run
 Necessary inventory >15 g

Nat. Phys. 18, 160-166 (2022)

- Electrons emitted from source in region with high B_s field travel adiabatically along field lines to analysing region with low field B_{\min}
- Only electrons with sufficient energy pass the potential barrier at the central plane with retarding potential, re-accelerated and detected

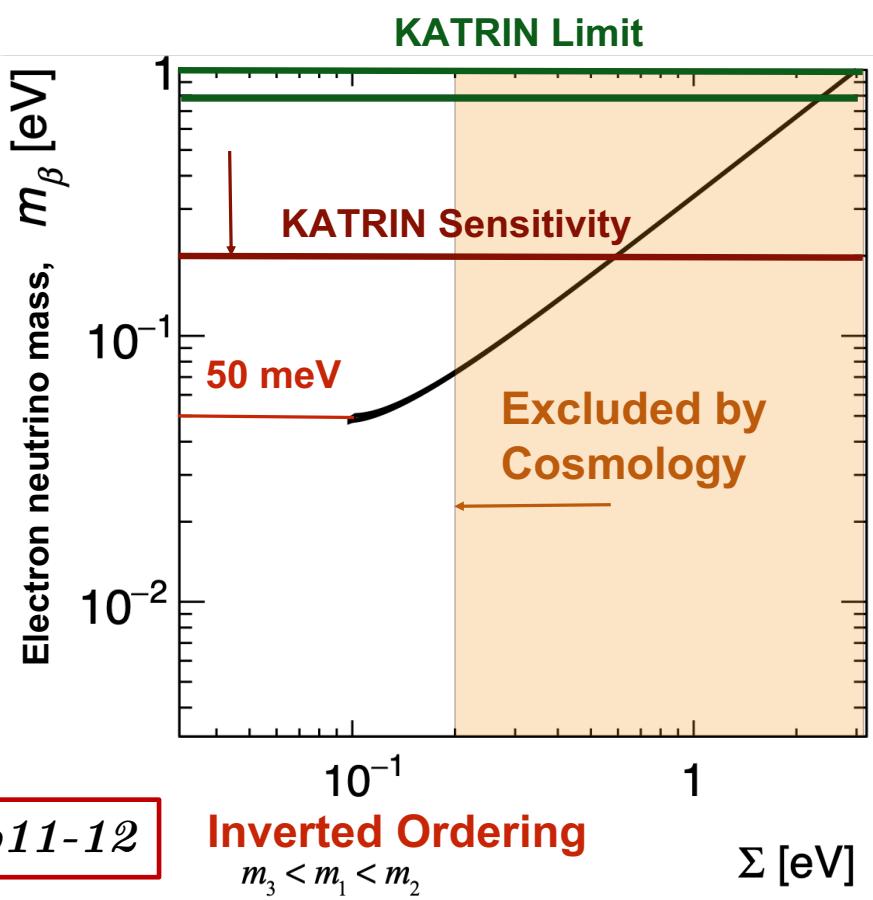

First sub-eV result, $m_\beta < 0.8$ eV c⁻² at 90%CL !

Nat. Phys. 18, 160-166 (2022)

Ultimate sensitivity 0.2 eV c⁻²

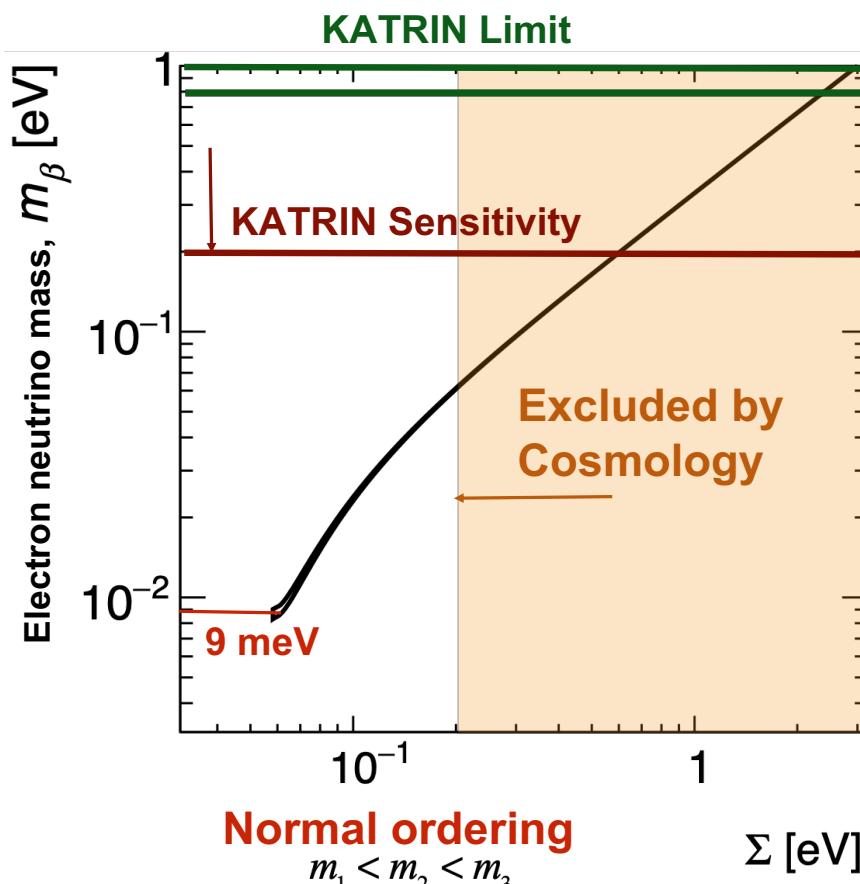

- Ultimate sensitivity ~ 0.2 eV
- MAC-E cannot be scaled up beyond **KATRIN**

see also p11-12

Inverted Ordering

$$m_3 < m_1 < m_2$$

Adapted from M. Agostini et al, Phys. Rev., D96(5):053001, 2017

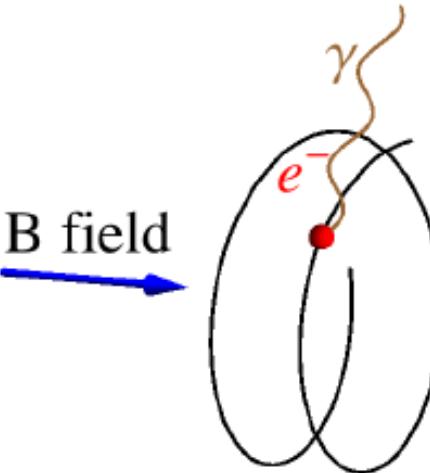

- Powerful constraints from cosmology but cannot replace **lab measurements**
- Kinematic" measurement of β -decay spectrum is the **only model independent method**
- Two clear sensitivity goals: **50 meV** for **I.O.** and **9 meV** for **N.O.**

"Guaranteed" observation if technology demonstrated

How to overcome present technology limitations?

A. Schawlow: "Never measure anything but frequency!"

$$f = \frac{1}{2\pi} \frac{eB}{m_e + E_{\text{kin}}/c^2}$$

$$f \cdot \frac{\Delta E}{E} \sim \Delta f; \quad \frac{\Delta f}{f} \sim 10^{-6}$$

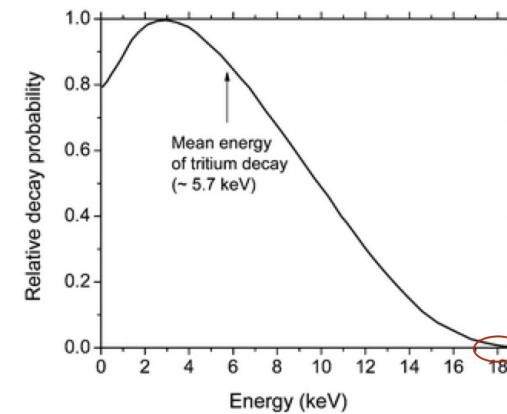

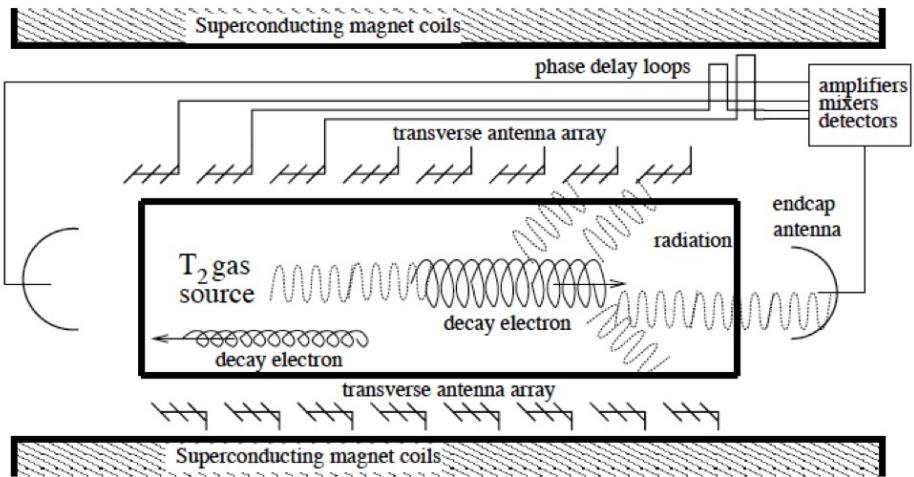

Determine energy of electron emitted in ${}^3\text{H}$ β -decay by measuring the frequency of EM radiation generated due to electron's cyclotron motion in magnetic field

Cyclotron Radiation Emission Spectroscopy (CRES)

Concept put forward by Project-8 Collaboration

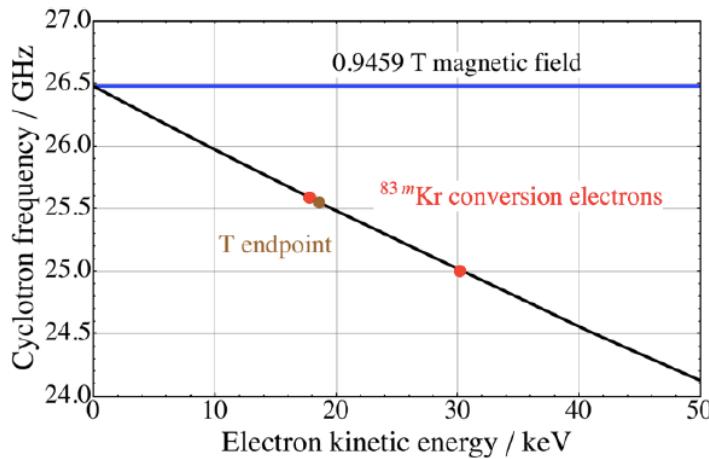

- Source **transparent** to microwave radiation
- **No losses** due to e- transport from source to detector
- Leverages exquisite **precision** in **frequency** techniques
- **Differential spectrum** measurement

Cyclotron Radiation Emission Spectroscopy (CRES) Concept

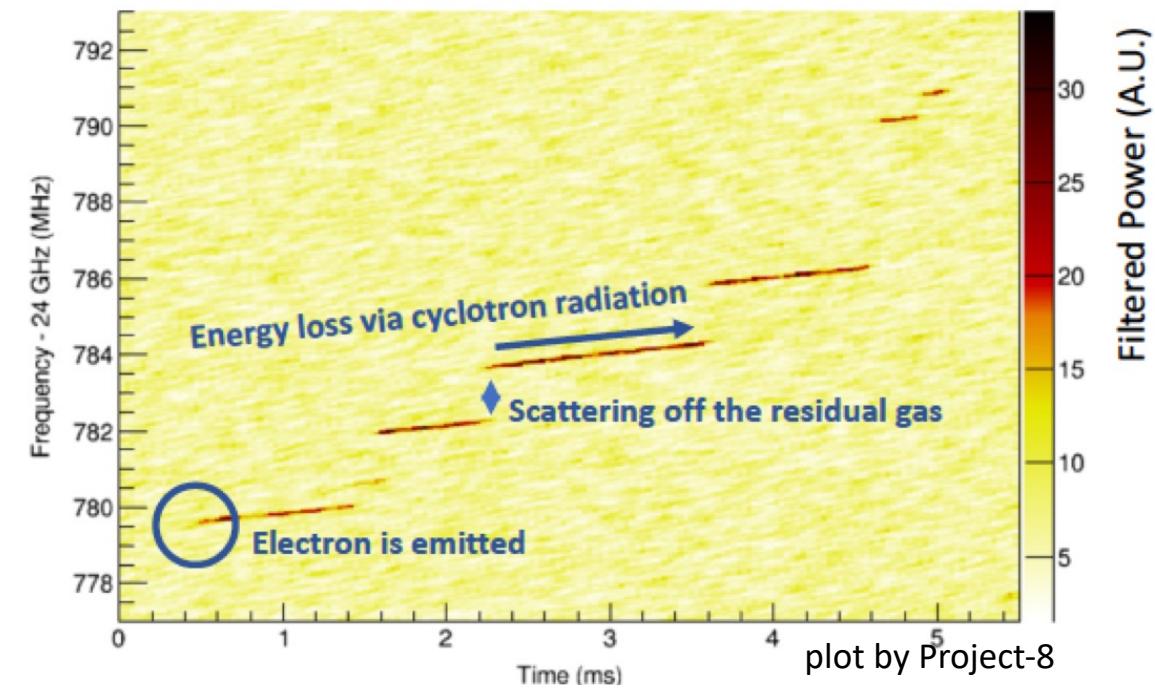

$$Q_\beta = 18.6 \text{ keV} \Rightarrow \sim 26 \text{ GHz}$$

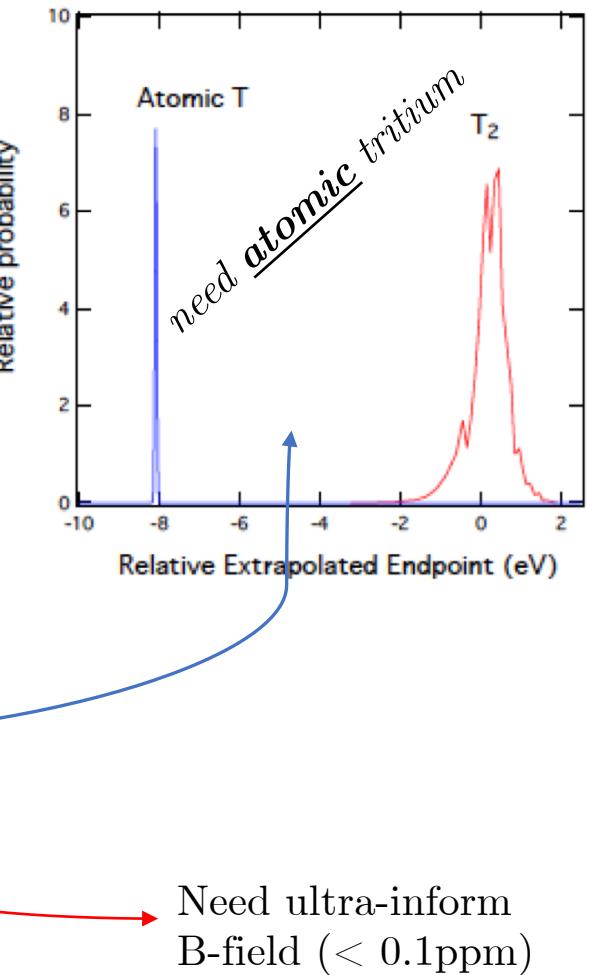

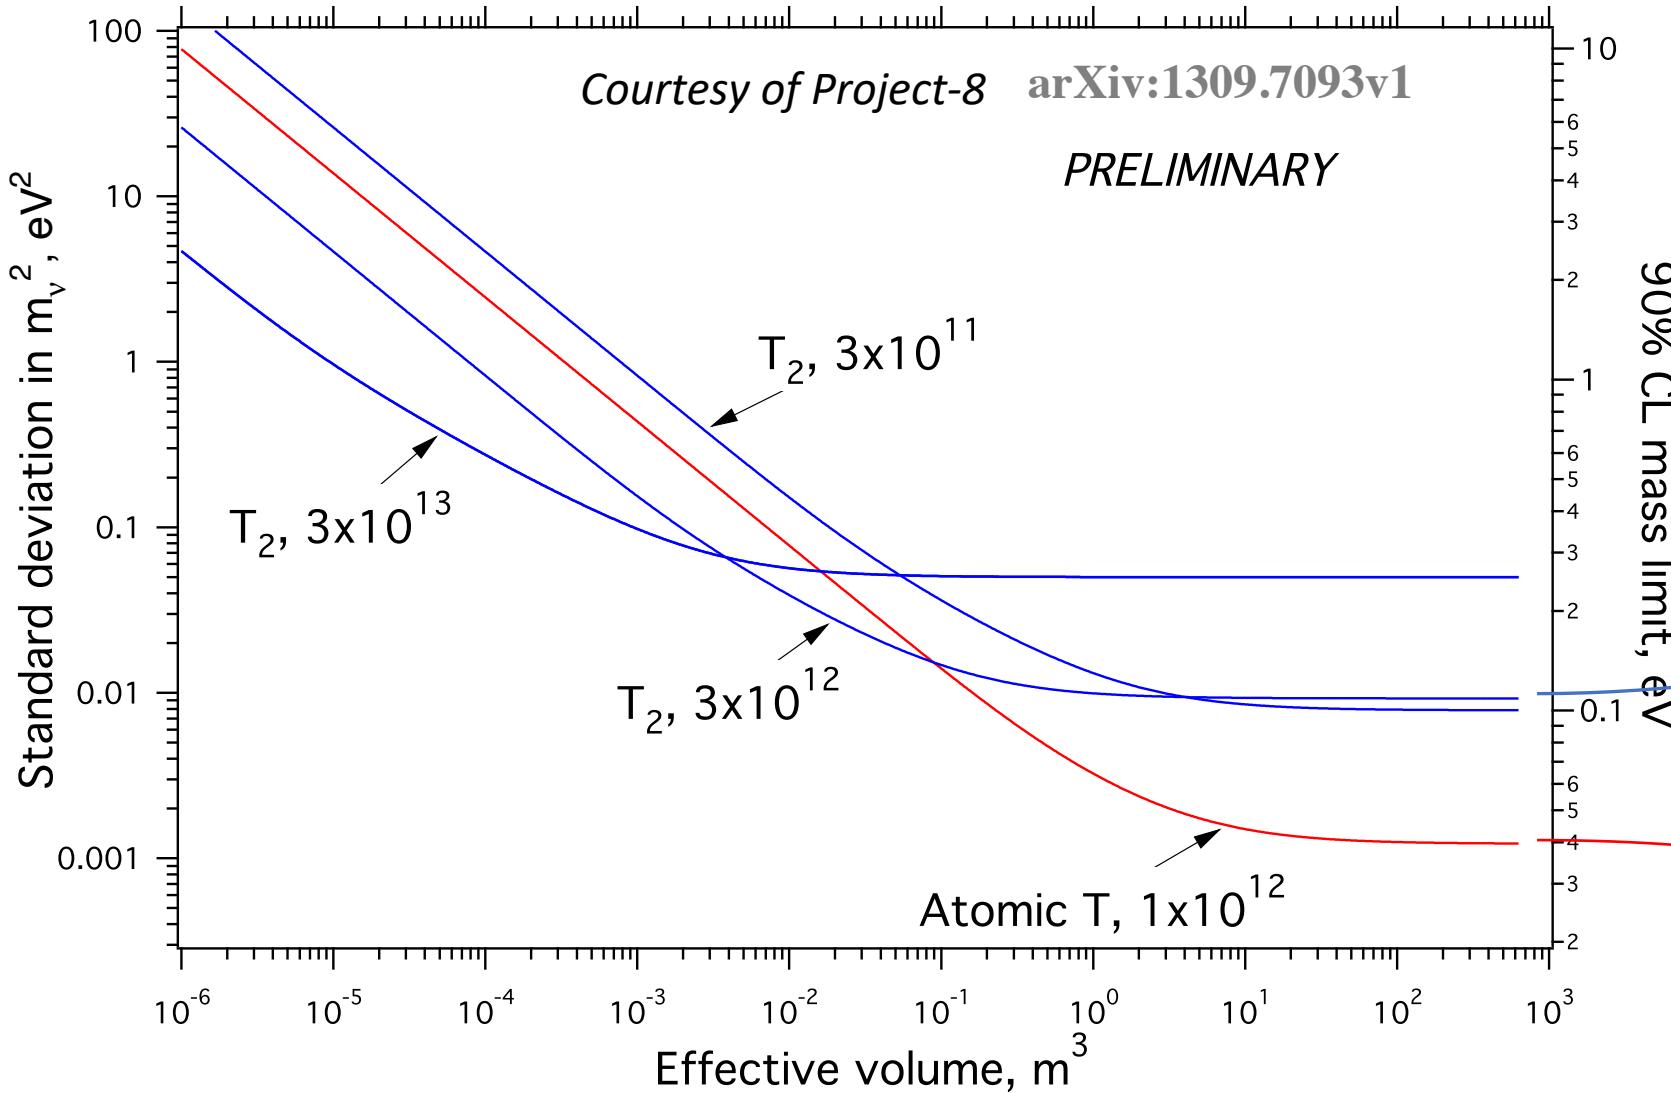

in 1 Tesla B-field

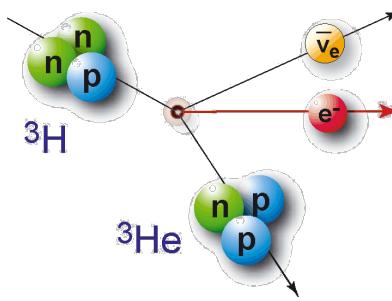

Proof of principle by Project-8 using $^{83\text{m}}\text{Kr}$ conversion electrons

CRES Sensitivity and Challenges

QTNM

Mission Neutrino mass measurement from ${}^3\text{H}$ β -decay via cyclotron radiation emission spectroscopy using latest advances in **quantum technologies**.

Strategy Phased approach: CRESDA* → CRESDA-Tritium → 100 meV → 50 meV → 10 meV

* CRES Demonstrator Apparatus

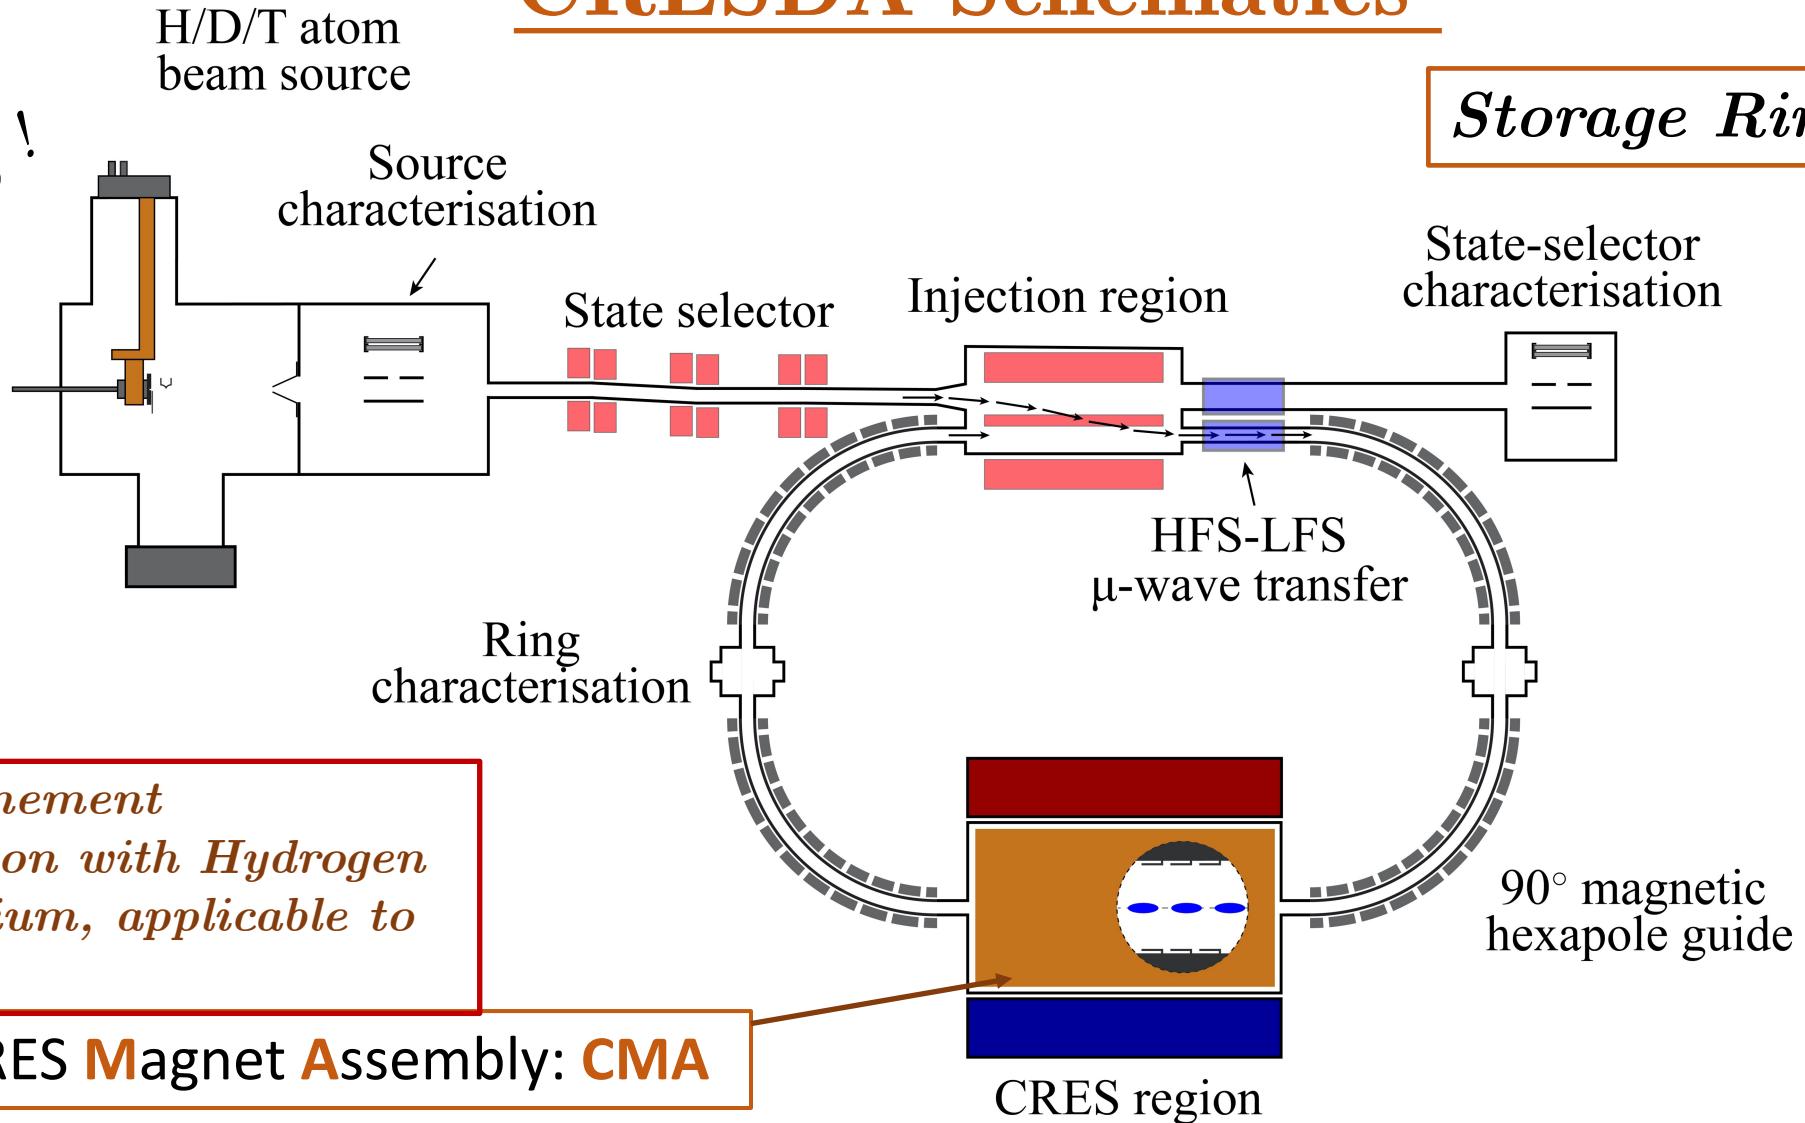

CRESDA Strategic Goals

quantum
technologies

- Production and confinement of H-atoms, $\geq 10^{12} \text{ cm}^{-3}$, scalable to $10^{20} \text{ atom} \times \text{yr}$ exposures
- B-field mapping with $< 1 \mu\text{T}$ abs precision and ~1mm spatial resolution
- CRES of $O(10\text{keV})$ electrons scalable to $\sim\text{m}^3$ detection volumes with $O(10\text{ppm})$ energy resolution and high detection efficiency

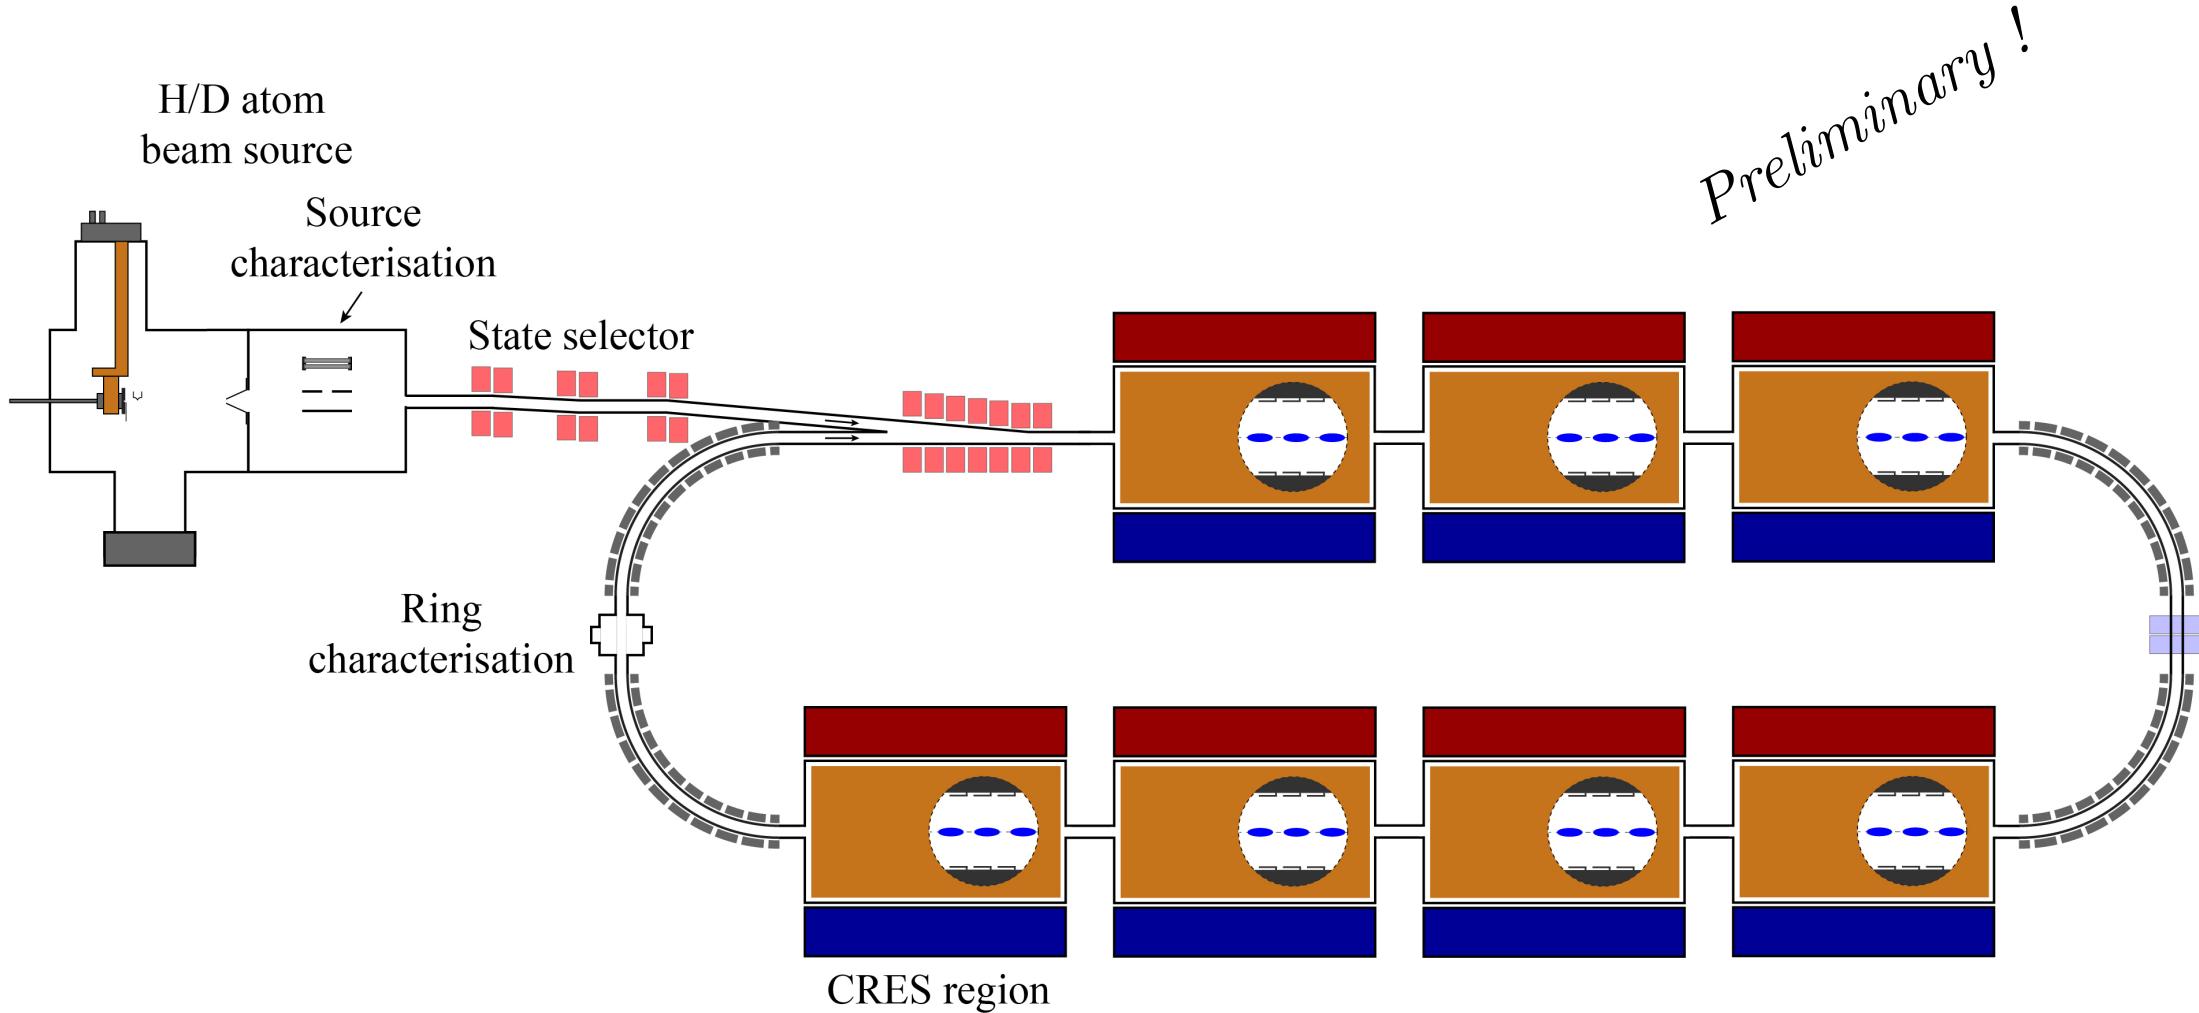

CRESDA Schematics

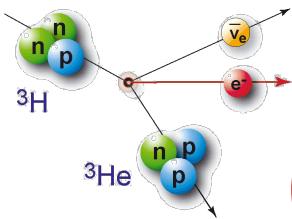

Preliminary !

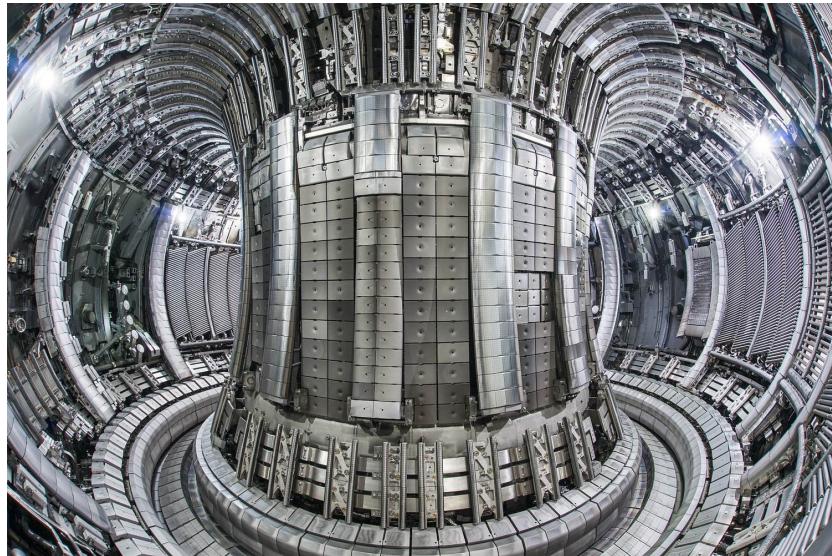

Storage Ring Concept

Scalability of Storage Ring Concept

QTNM

Future Outlook *(very tentative)*

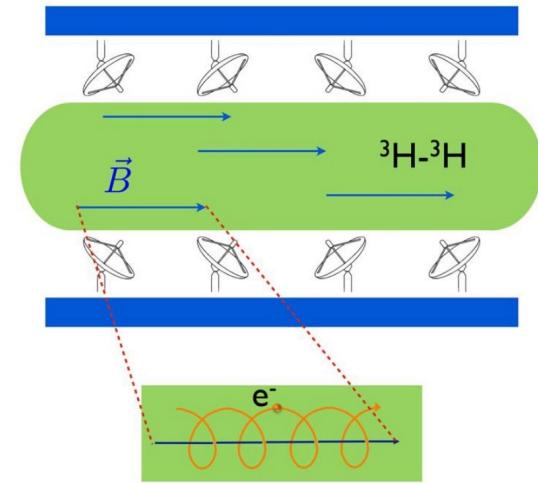

- Current project: 2021-2024
 - Technology demonstration with Hydrogen and Deuterium, scalable to Tritium (ongoing collaboration with Culham)
- Next step. 2025-2029
 - Moving CRESDA to a Tritium facility (focus on Culham)
 - Tritium phase demonstration
 - $O(eV)$ sensitivity
- "Ultimate" international project > 2029
 - Consolidate technological breakthroughs (QTNM, Project-8, KATRIN...) to build and operate a detector with a phased sensitivity: $100 \text{ meV} \Rightarrow 50 \text{ meV} \Rightarrow 10 \text{ meV}$ plus sterile neutrino programme

What kind of frequencies are we interested in? How much power can we expect to detect?

Tritium endpoint electron has $E_k \approx 18.6 \text{ keV} = 2.980\,05 \times 10^{-14} \text{ J}$

Frequency of radiation given by

$$f = \frac{1}{2\pi} \frac{eB}{m_e + E_k/c^2}$$

If our decay electrons are in a **1 Tesla magnetic field** we find:

$$f = \frac{1}{2\pi} \frac{1.602\,18 \times 10^{-19} \text{ C} \cdot 1 \text{ T}}{9.109\,384 \times 10^{-31} \text{ kg} + 2.980\,05 \times 10^{-14} \text{ J}/(2.997\,92 \times 10^8 \text{ m/s})^2}$$
$$\approx 27 \text{ GHz}$$

Therefore, we are interested in detecting **microwaves** with a **wavelength of roughly 1 cm**

Suitable for detection with either **antenna(s)**, **waveguide** or **resonant cavity**

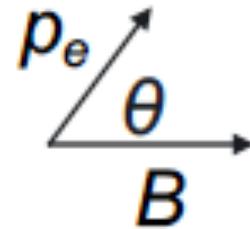

What kind of frequencies are we interested in? How much power can we expect to detect?

Total radiated power given by

$$P = \frac{2\pi e^2 f_0^2}{3\epsilon_0 c} \frac{\beta^2 \sin^2 \theta}{1 - \beta^2}$$

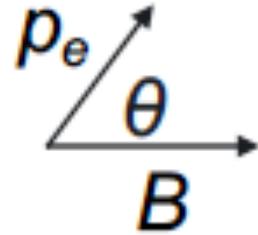

Our endpoint electrons are mildly relativistic $\gamma = 1 + \frac{E_k}{mc^2} = 1.0364$ and $\beta = 0.263$

θ is 'pitch angle' - angle between B field direction and electron momentum

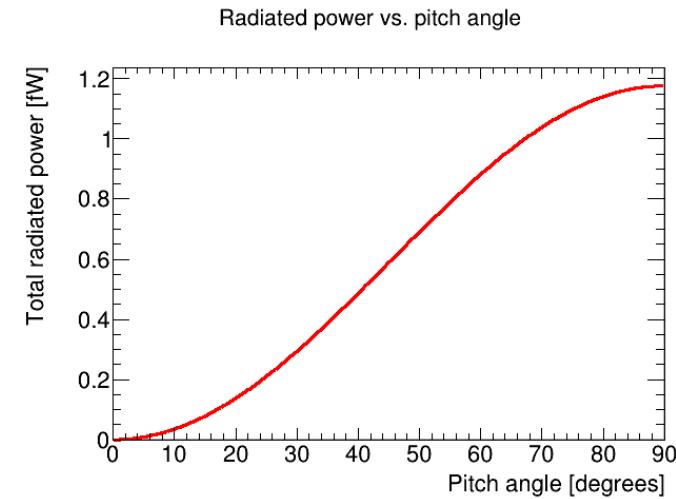

$$f_0 = \frac{1}{2\pi} \frac{eB}{m} = 27.9925 \text{ GHz} \quad \text{and} \quad P = 1.17 \text{ fW} \quad \text{for } B = 1 \text{ T and } \theta = \frac{\pi}{2}$$

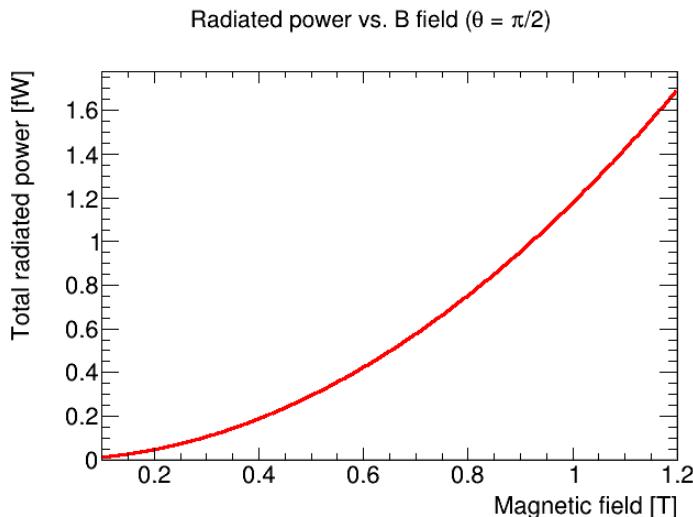

What kind of frequencies are we interested in? How much power can we expect to detect?

$$P = \frac{2\pi e^2 f_0^2}{3\epsilon_0 c} \frac{\beta^2 \sin^2 \theta}{1 - \beta^2}$$

Those electrons with **pitch angles close to 90°** are the **most detectable**

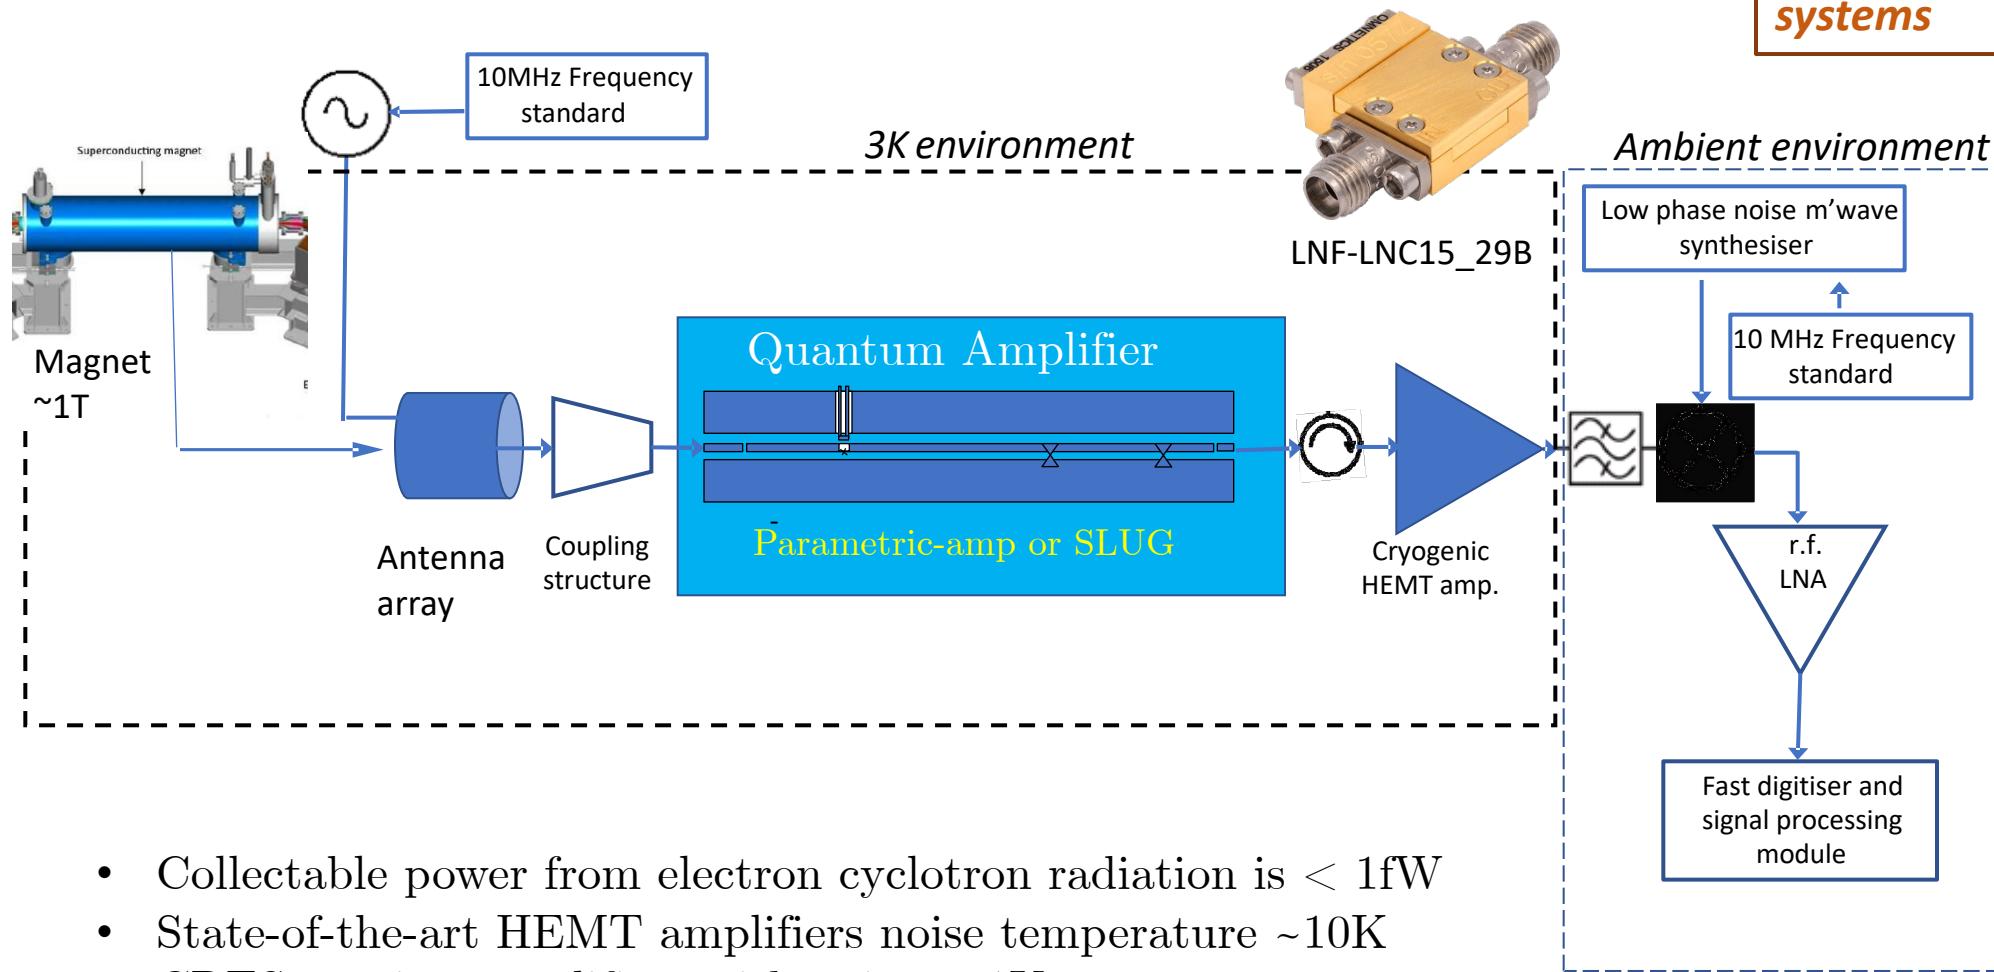

$$\xleftarrow{\hspace{-1cm}} P \propto B^2$$

Small radiated power necessitates a strong magnetic field as well as amplifiers with very low noise

Cyclotron Radiation Readout in QTNM

From devices to quantum noise limited microwave **detection systems**

- Collectable power from electron cyclotron radiation is $< 1\text{fW}$
- State-of-the-art HEMT amplifiers noise temperature $\sim 10\text{K}$
- CRES requires amplifiers with noise $\leq 1\text{K}$

Quantum Amplifiers!

*See Lecture
on Quantum
Electronics
Wed at
11:30*

What sort of bandwidth are we interested in?

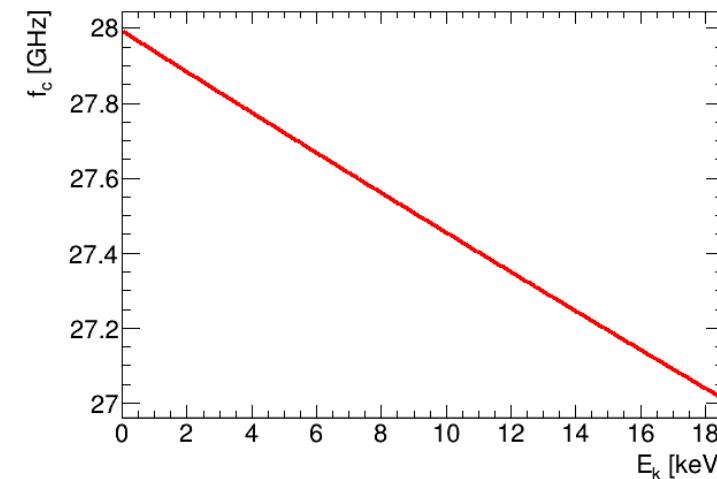

$$f = \frac{1}{2\pi} \frac{eB}{m + E_k/c^2} = \frac{eB}{2\pi} \left(\frac{E}{c^2} \right)^{-1}$$

Entire decay spectrum covers a frequency range of about 1 GHz

$$\frac{df}{dE} = -\frac{eBc^2}{2\pi} E^{-2}$$

B = 1 T and kinetic energy = 18.6 keV

Therefore $\frac{df}{dE} = 3.18 \times 10^{23} \text{ Hz J}^{-1} = 51 \text{ kHz eV}^{-1}$

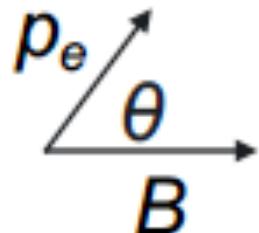

So to measure the last 200 eV of spectrum we require a bandwidth of roughly 10 MHz
Amplifiers and readout chain must be capable of operating over this bandwidth

How long do we need to observe our electrons for?

We have $\frac{df}{dE} = 51 \text{ kHz eV}^{-1}$ and require $\Delta E = 1 \text{ eV}$. Therefore $\Delta f = 51 \text{ kHz}$

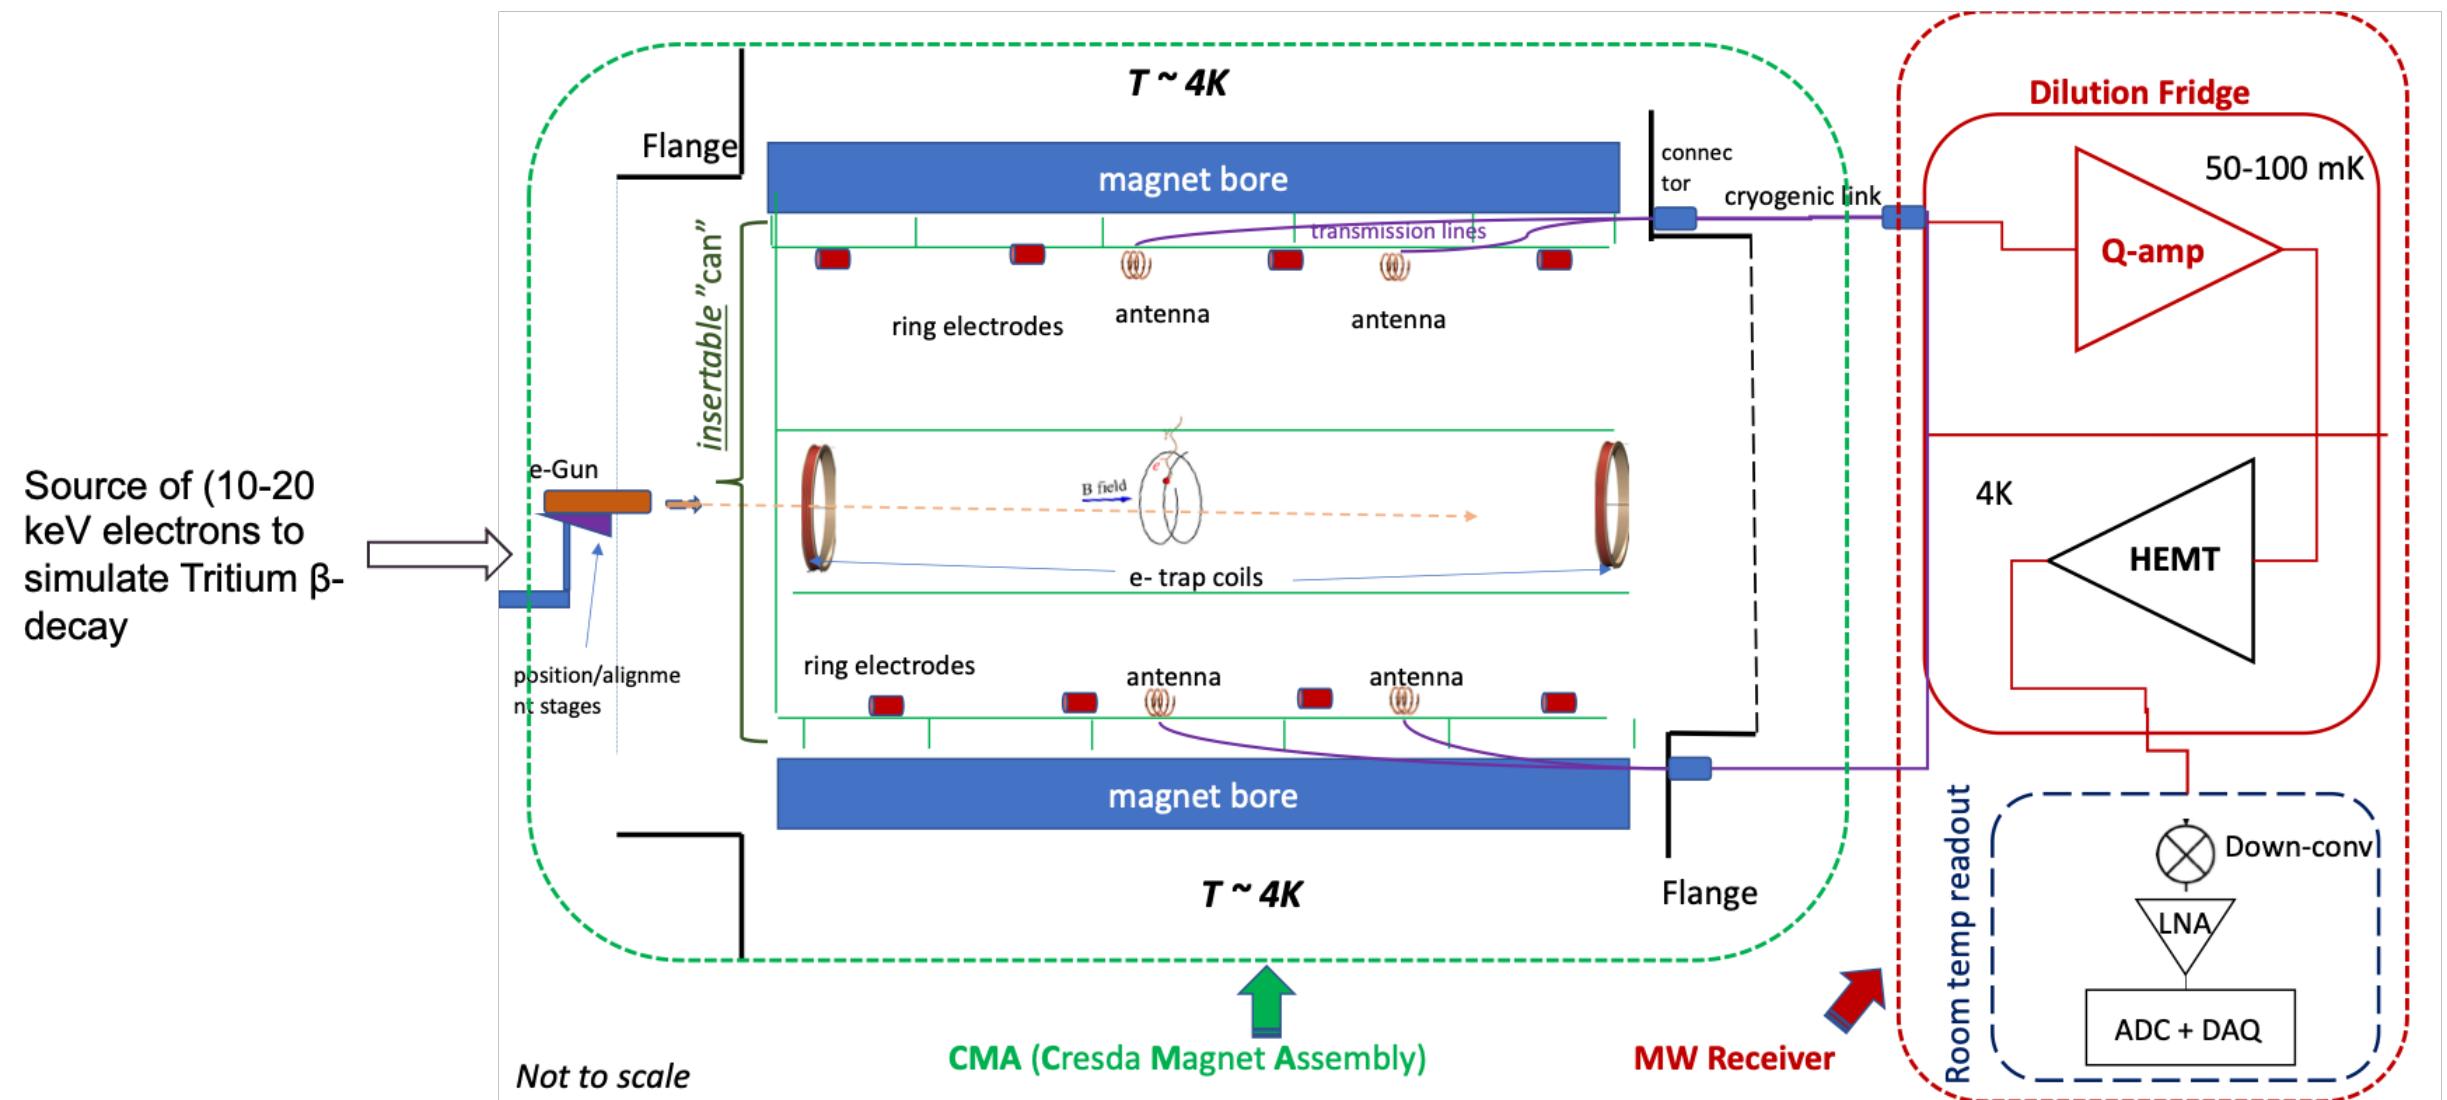

$$t_{\text{obs}} \sim \frac{1}{\Delta f} \quad \therefore t_{\text{obs}} \geq 20 \mu\text{s}$$

An endpoint electron with a **pitch angle of 89°** will travel a distance of $v t \cos \theta = 0.263c \cdot \cos(89^\circ) \cdot 20 \mu\text{s} = 275 \text{ m}$ parallel to the magnetic field!

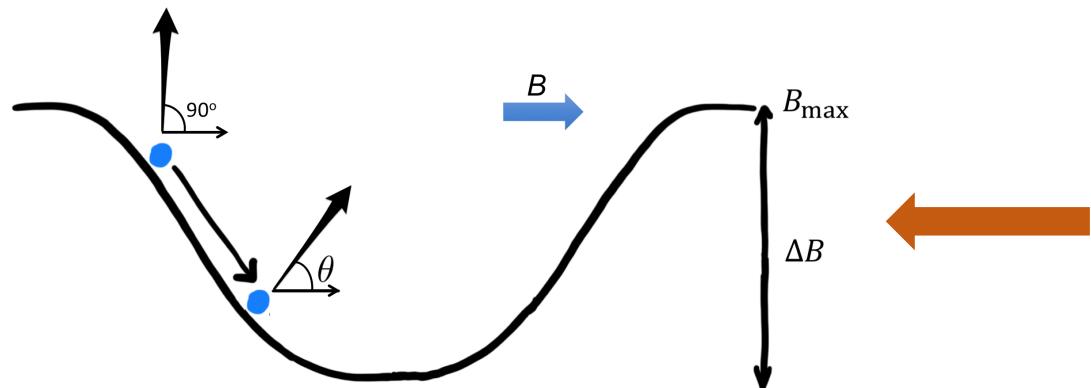

Solution: We need to contain our decay electrons within a 'no-work' trap so they can be observed for the required amount of time

CRES Magnet Assembly: CMA

Magnetic trapping of electrons

- Need to trap electrons to achieve required resolution and collect enough power

'No work trap' is **magnetic bottle**

Local minimum in magnitude of background B field

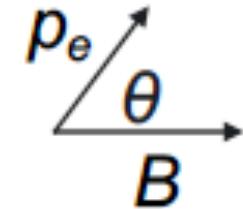

Ashtari Esfahani *et al.*, Phys. Rev. C 99, 055501 (2019)

Only electrons with **pitch angles** above a certain value are **trapped**

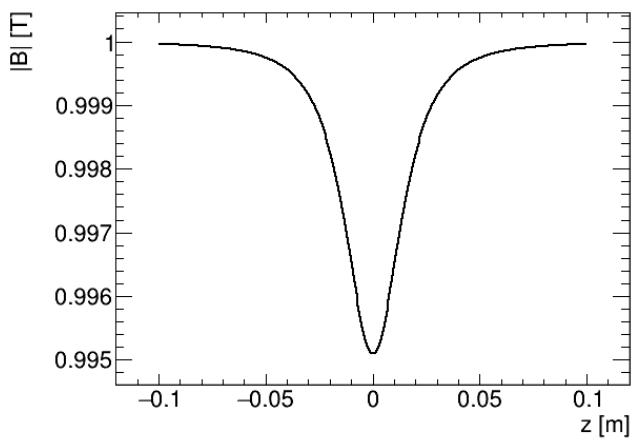

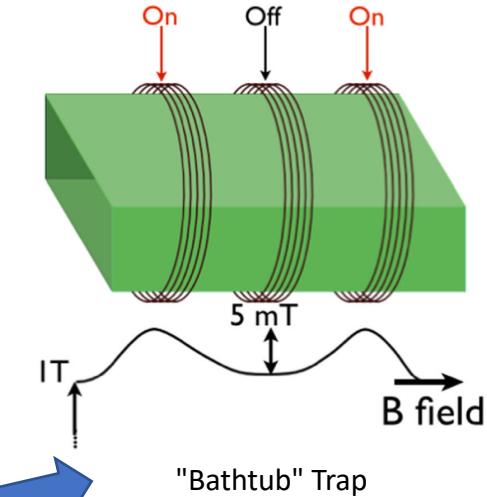

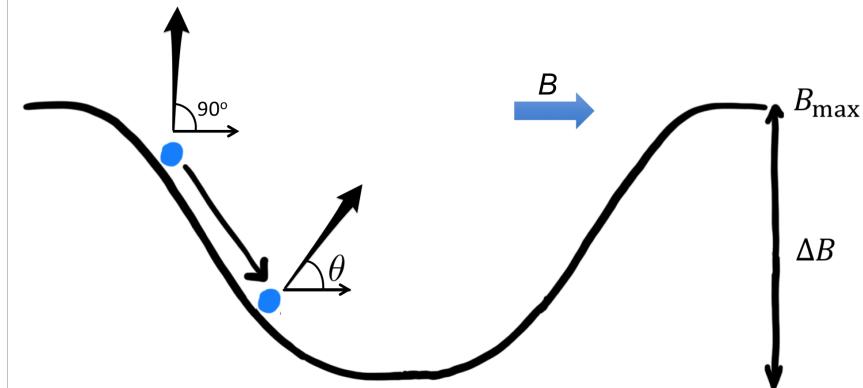

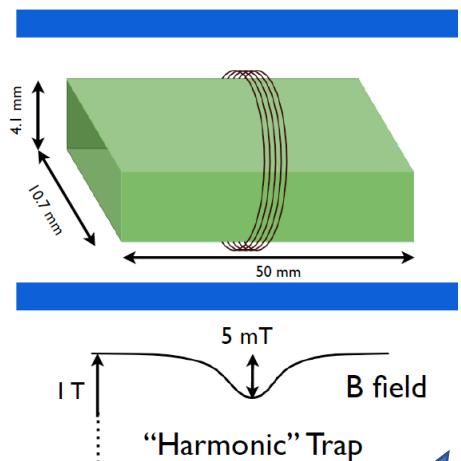

These trapped electrons climb up the magnetic field potential until eventually their pitch angle becomes 90° and they change direction

Trapping condition given by:

$$\theta_{\text{bot}} \geq \arcsin \left(\sqrt{1 - \frac{\Delta B}{B_{\max}}} \right)$$

Electron trapping

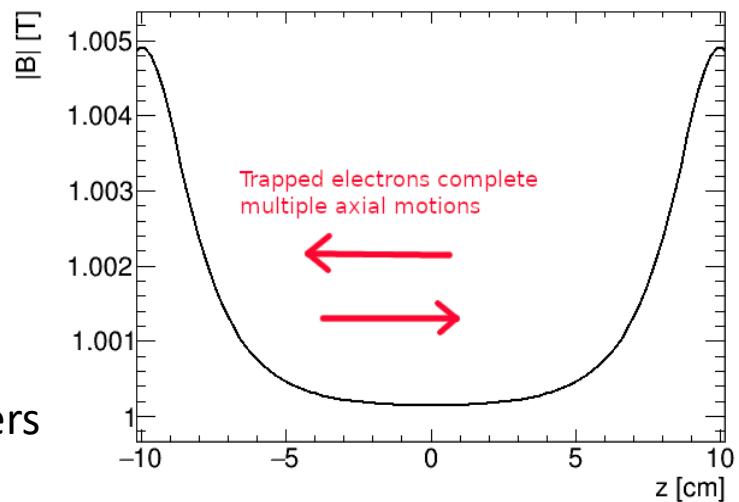

A **5mT** trap in a **1T** background field gives $\theta_{\text{bot}} \geq 86^\circ$

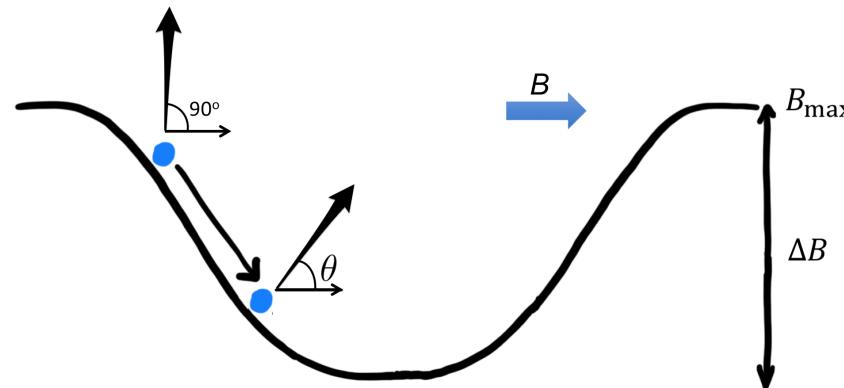

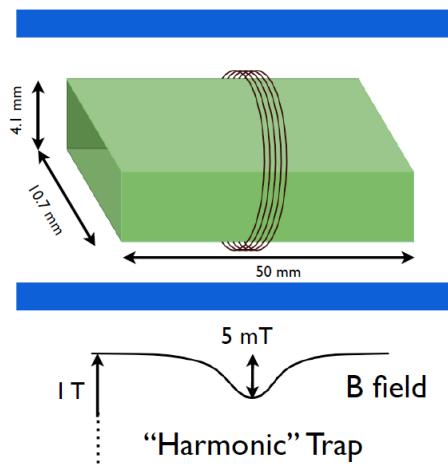

Trapped fraction

$$\eta_{\text{trapped}} = \sin \delta\theta, \quad \delta\theta = \arccos \left(\sqrt{1 - \frac{\Delta B}{B_{\max}}} \right)$$

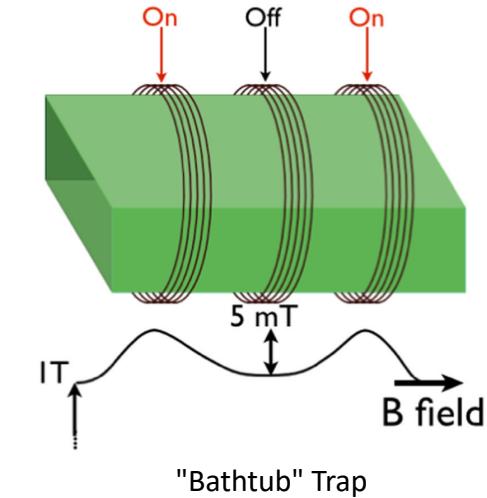

Only **7%** of electrons **trapped** with above parameters

Why not deeper traps?

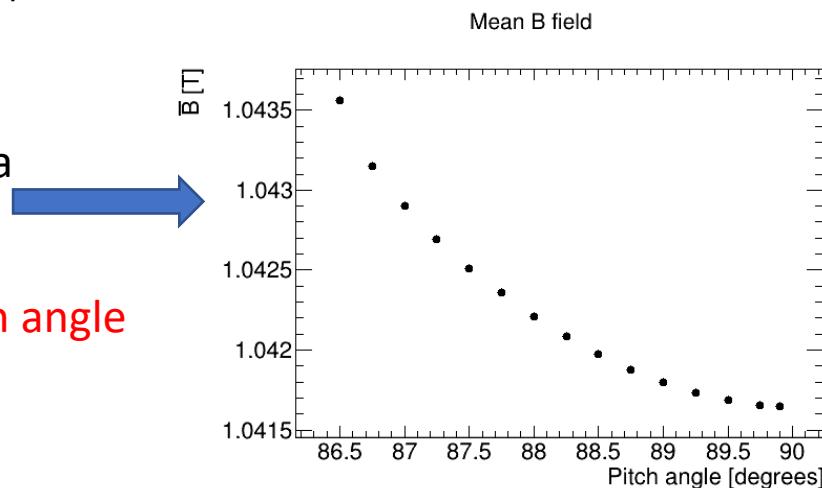

Ashtari Esfahani *et al.*, Phys. Rev. C 99, 055501 (2019)

- Trade-off between **efficiency** and **resolution**
- Cyclotron frequency depends on **average B field** experienced by electron
- “Deep” trap – more electrons trapped but poorer frequency(energy) resolution
- “Shallow” trap – better resolution but fewer electrons trapped

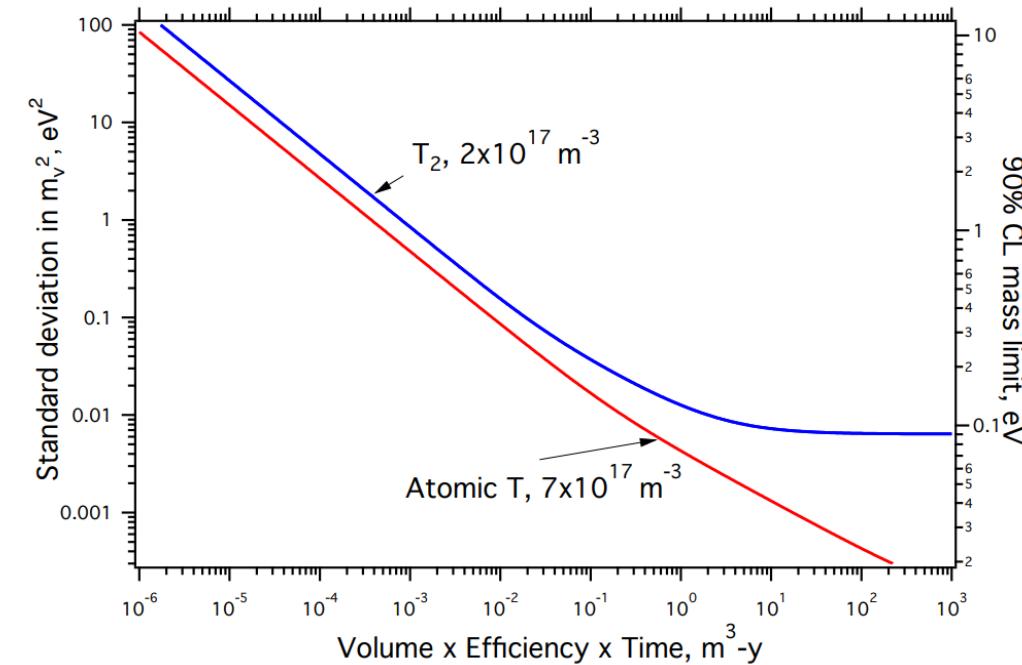

Difference between min. and max. average B field equates to a frequency(energy) difference of **54 MHz(1060 eV)**

Crucial that we use **signal features** to reconstruct electron **pitch angle**

CRES: targets and challenges

- The 'final' neutrino mass experiment (ensuring a 'guaranteed observation' of neutrino mass) will require:
 - Energy resolution, $\Delta E \sim 0.1$ eV
 - Production of atomic tritium source
 - Trapping and observation of 10^{20} tritium atoms at one time for ~ 1 year
 - For atomic density of 10^{19} m^{-3} , could be realised with a 3 year run, 75% volume efficiency, 10% pitch angle efficiency and 44 m^3 volume
 - Large volumes with high field uniformity and good acceptance challenging
 - Trap a range of pitch angles without degradation of ΔE
- CRESDA provides a pathway towards this final experiment
 - Demonstration of atomic trapping with H/D atoms
 - Detection of CRES signals from electrons around tritium endpoint energy
 - Testing of possible CRES detection options (antennas, waveguides, cavities)
 - Use of quantum-limited electronics to overcome weak signal power
 - High-precision magnetic field mapping

A highly recommended Review
from which many plots of this
Lecture are taken:

Phys. Rep. 914 1-54 (2021)

Possible Questions for the Tutorial Session (on Overview part)

Q1.1 Why inverted mass ordering is “favourable” for a positive neutrino mass detection? Why m_β cannot be zero in any scenario if $m_{1,2,3} \neq 0$, but $m_{\beta\beta}$ can be?

Q1.2 If Cosmology appears to deliver most sensitive absolute neutrino mass measurement why do we need other methods?

Q1.3 What are pros and cons of the three methods m_β measurement using β -decay?

Q1.4 Why KATRIN sensitivity is limited to 0.2 eV? What limits the sensitivity of the MAC-E method?

Q1.5 How do we know with “pitch angles” β -decay electrons are trapped in a magnetic bottle?

Q1.6 How is the sensitivity of the β -decay method of measuring the neutrino mass is calculated (back-of-the envelope)?

Q1.7 How can the B-field homogeneity be controlled/measured at a sub-ppm level?

Q1.8 Is a fully-fledged fusion centre necessary for a neutrino mass experiment?

Are there other options if CCFE not available?
