## Spinning primordial black holes in a matter dominated universe

Tuesday 23 May 2023 13:45 (15 minutes)

Interest in primordial black holes (PBHs) has spiked since the first detection of gravitational waves, and a few mass windows remain in which PBHs may still make up an appreciable part of dark matter. In a matter dominated universe, e.g. in the case of a first-order QCD phase transition, PBH production is enhanced and PBHs may have large dimensionless spins. We investigate the re-entry and collapse of superhorizon perturbations with initial dimensionless spins of  $\chi_0^{\xi} \sim 0.1$  in this setting using full 3+1D numerical relativity simulations. We find that PBHs are formed with dimensionless spins  $\chi_{\rm PBH}$  smaller than but the same order of magnitude as  $\chi_0^{\xi}$  and argue this suggests no PBHs with  $\chi_{\rm PBH} > 0.5$  are produced. Furthermore, we find that the addition of angular momentum only has a minor effect on the PBH mass and accretion rate. Additionally, we discuss apparent black hole horizons and cosmological horizons in the context of numerical relativity simulations of expanding spacetimes.
