PICO_analysis chain

- **Cameras:**
of bubbles and their location.
- **Acoustic signal and pressure trace:**
time of bubble's birth.
- **Position correction in acoustics:**
level2 acoustic analysis
(Alpha discrimination)
- **Pressure trace fit:**
level2 Dytran analysis
(event validity and confirmation on multiplicity)

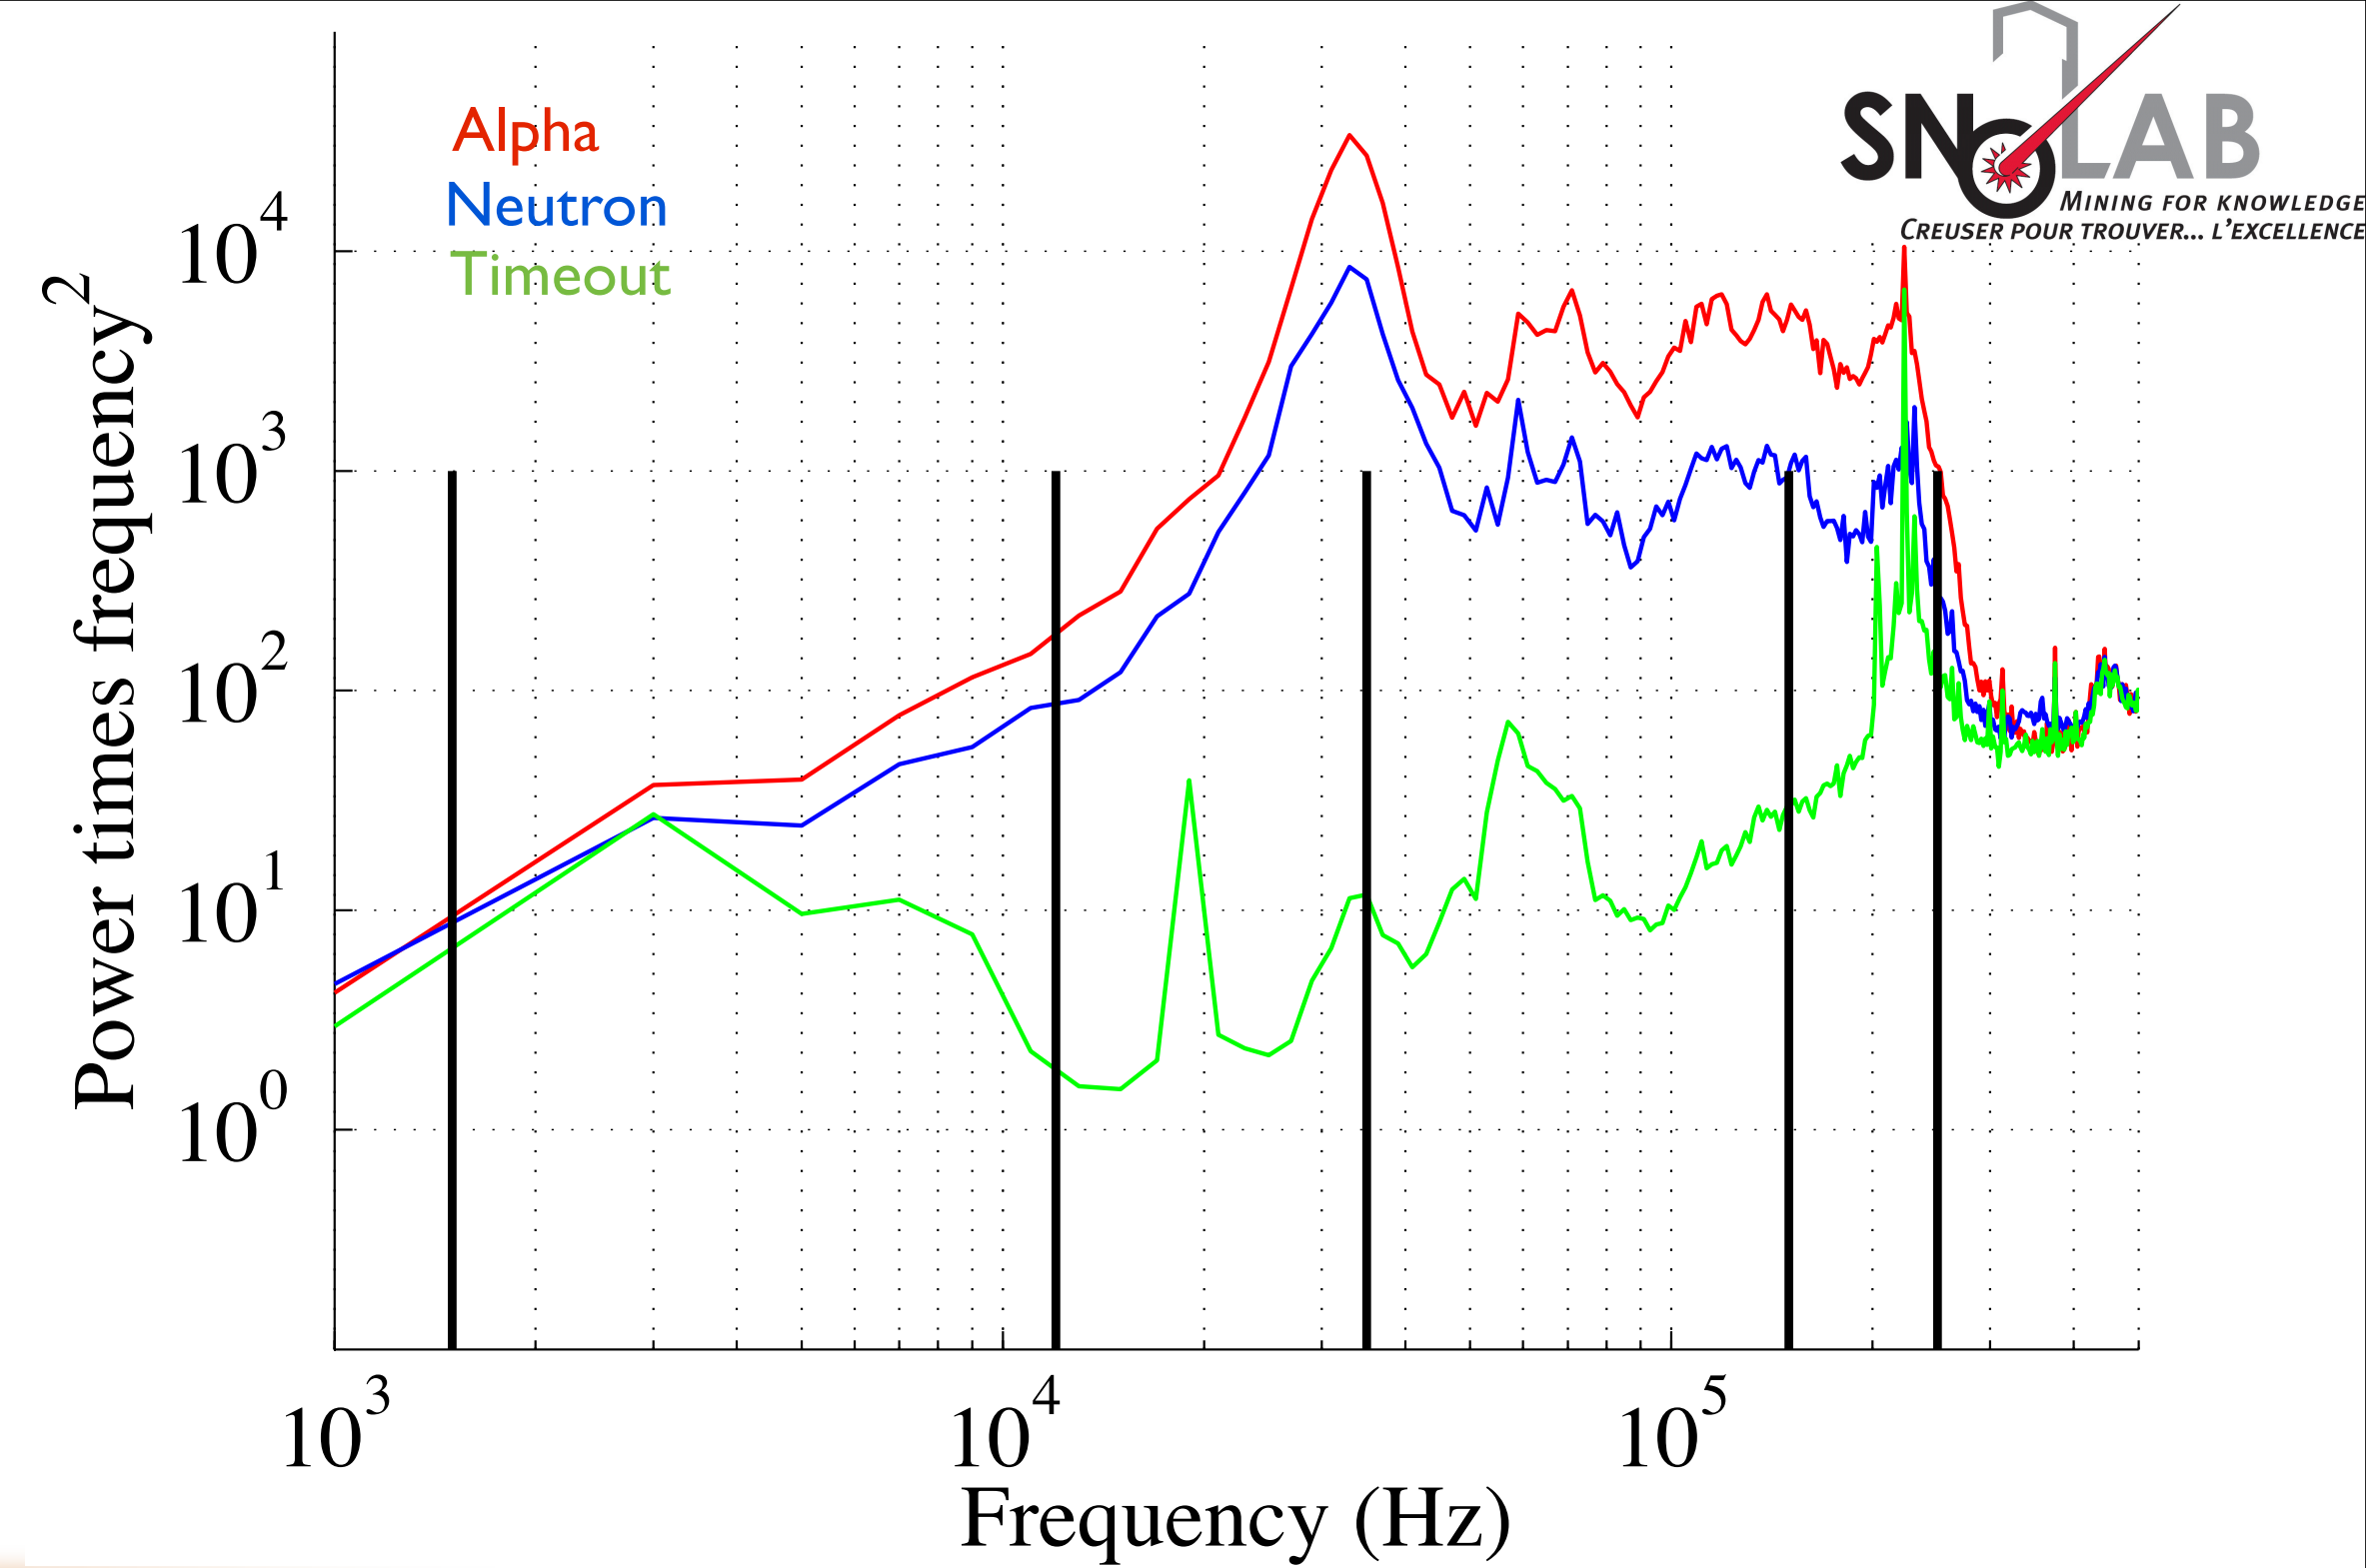

23 bubble AmBe neutron event:

- C_3F_8 offers high bubble nucleation efficiency.
- 60% neutron events have multiple bubbles.
- SNOLAB + Water shielding.
- Currently, no multiples seen in the background data.

PICO_alphas

- Discovery of acoustic discrimination against alphas (Aubin et al., New J. Phys.10:103017, 2008)
- Alphas deposit their energy in a few tens of micrometers whereas nuclear recoils energy is over tens of nanometers

Observable bubble ~mm

~40 μm

~50 nm

Daughter heavy nucleus
(~100 keV)

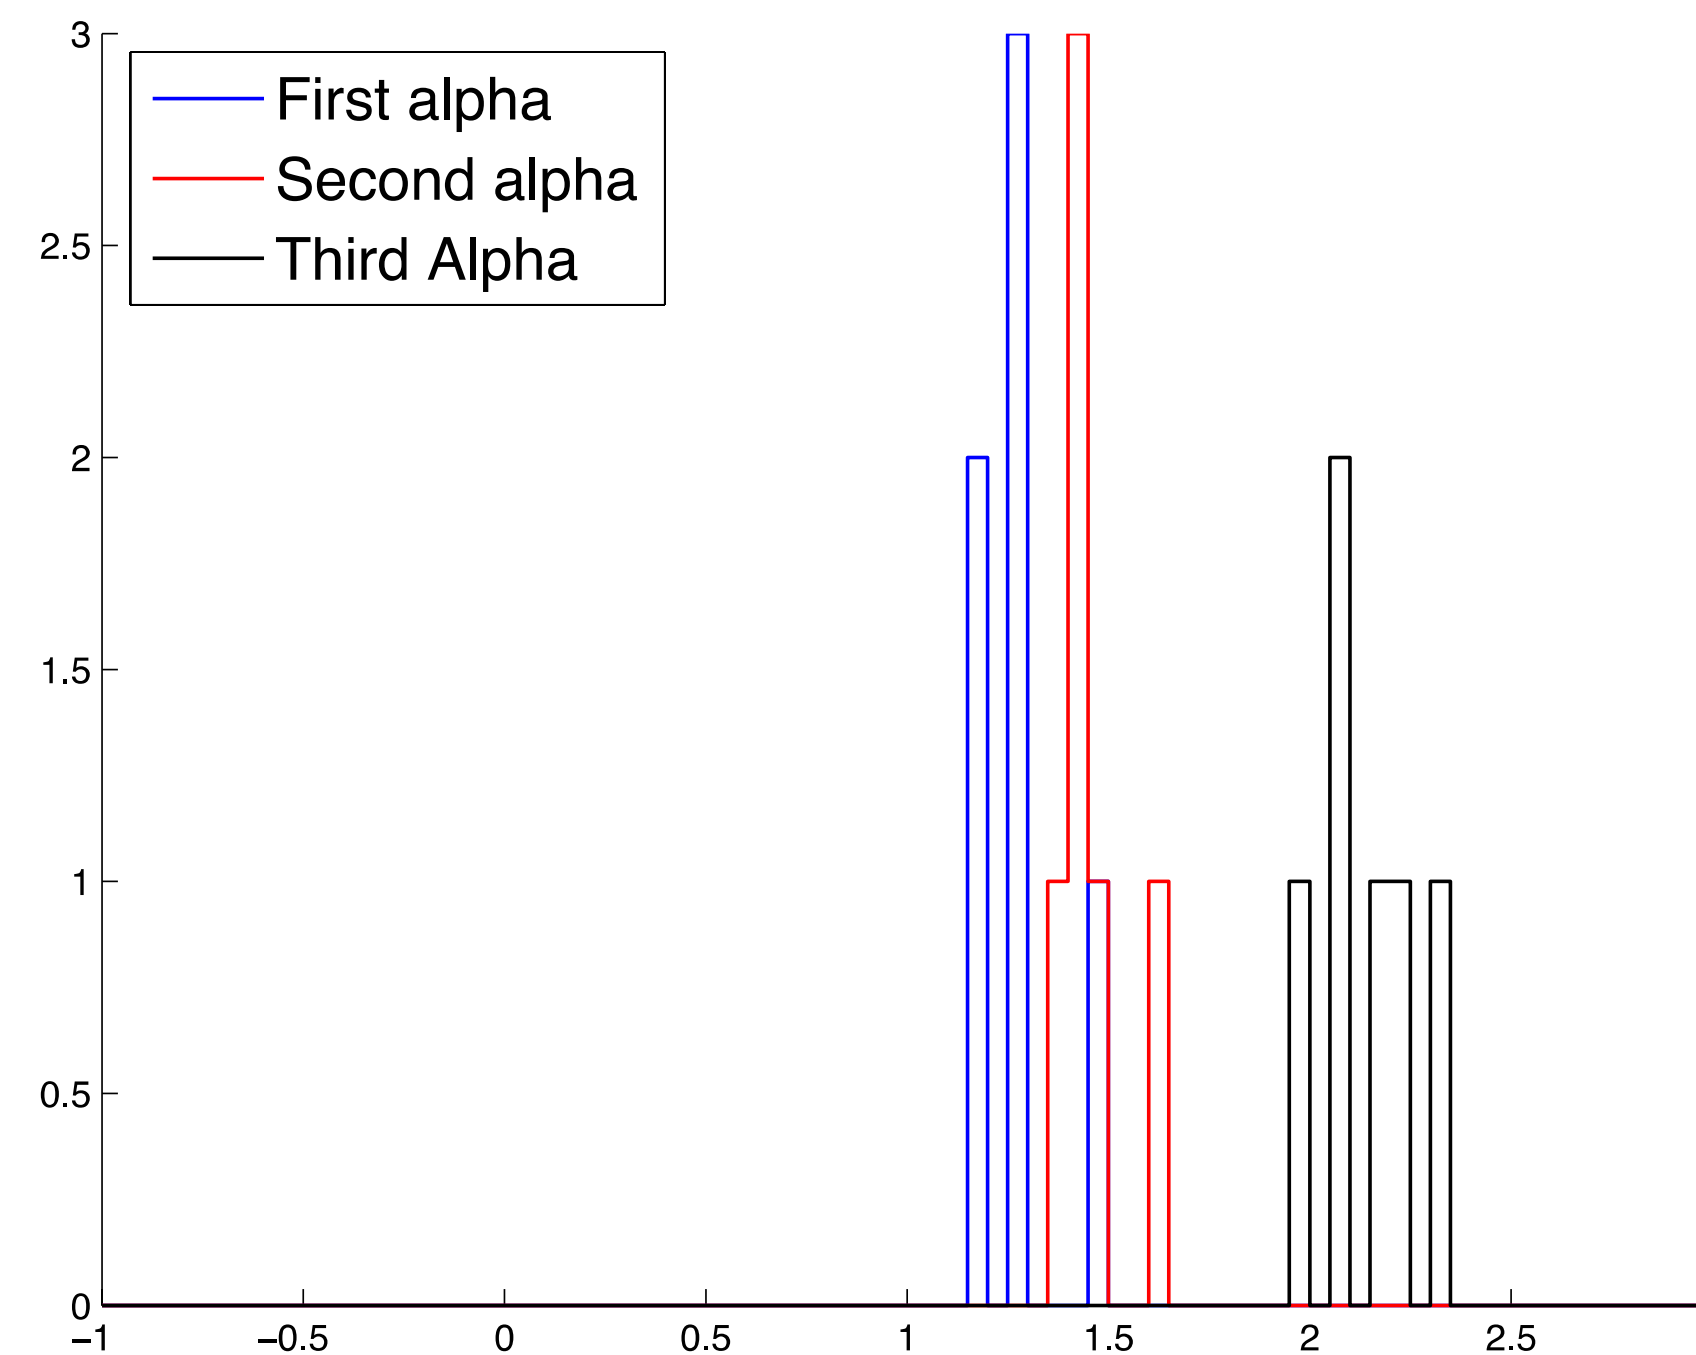

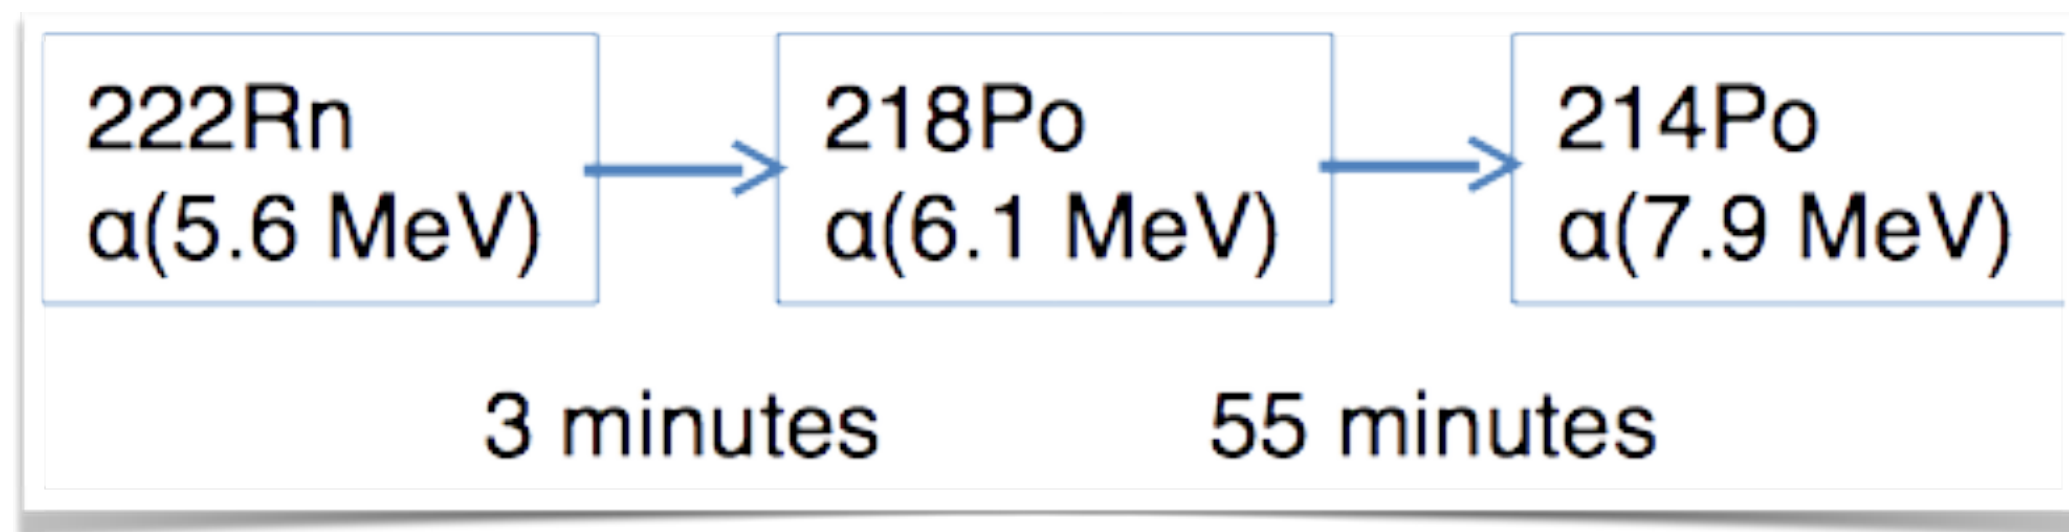

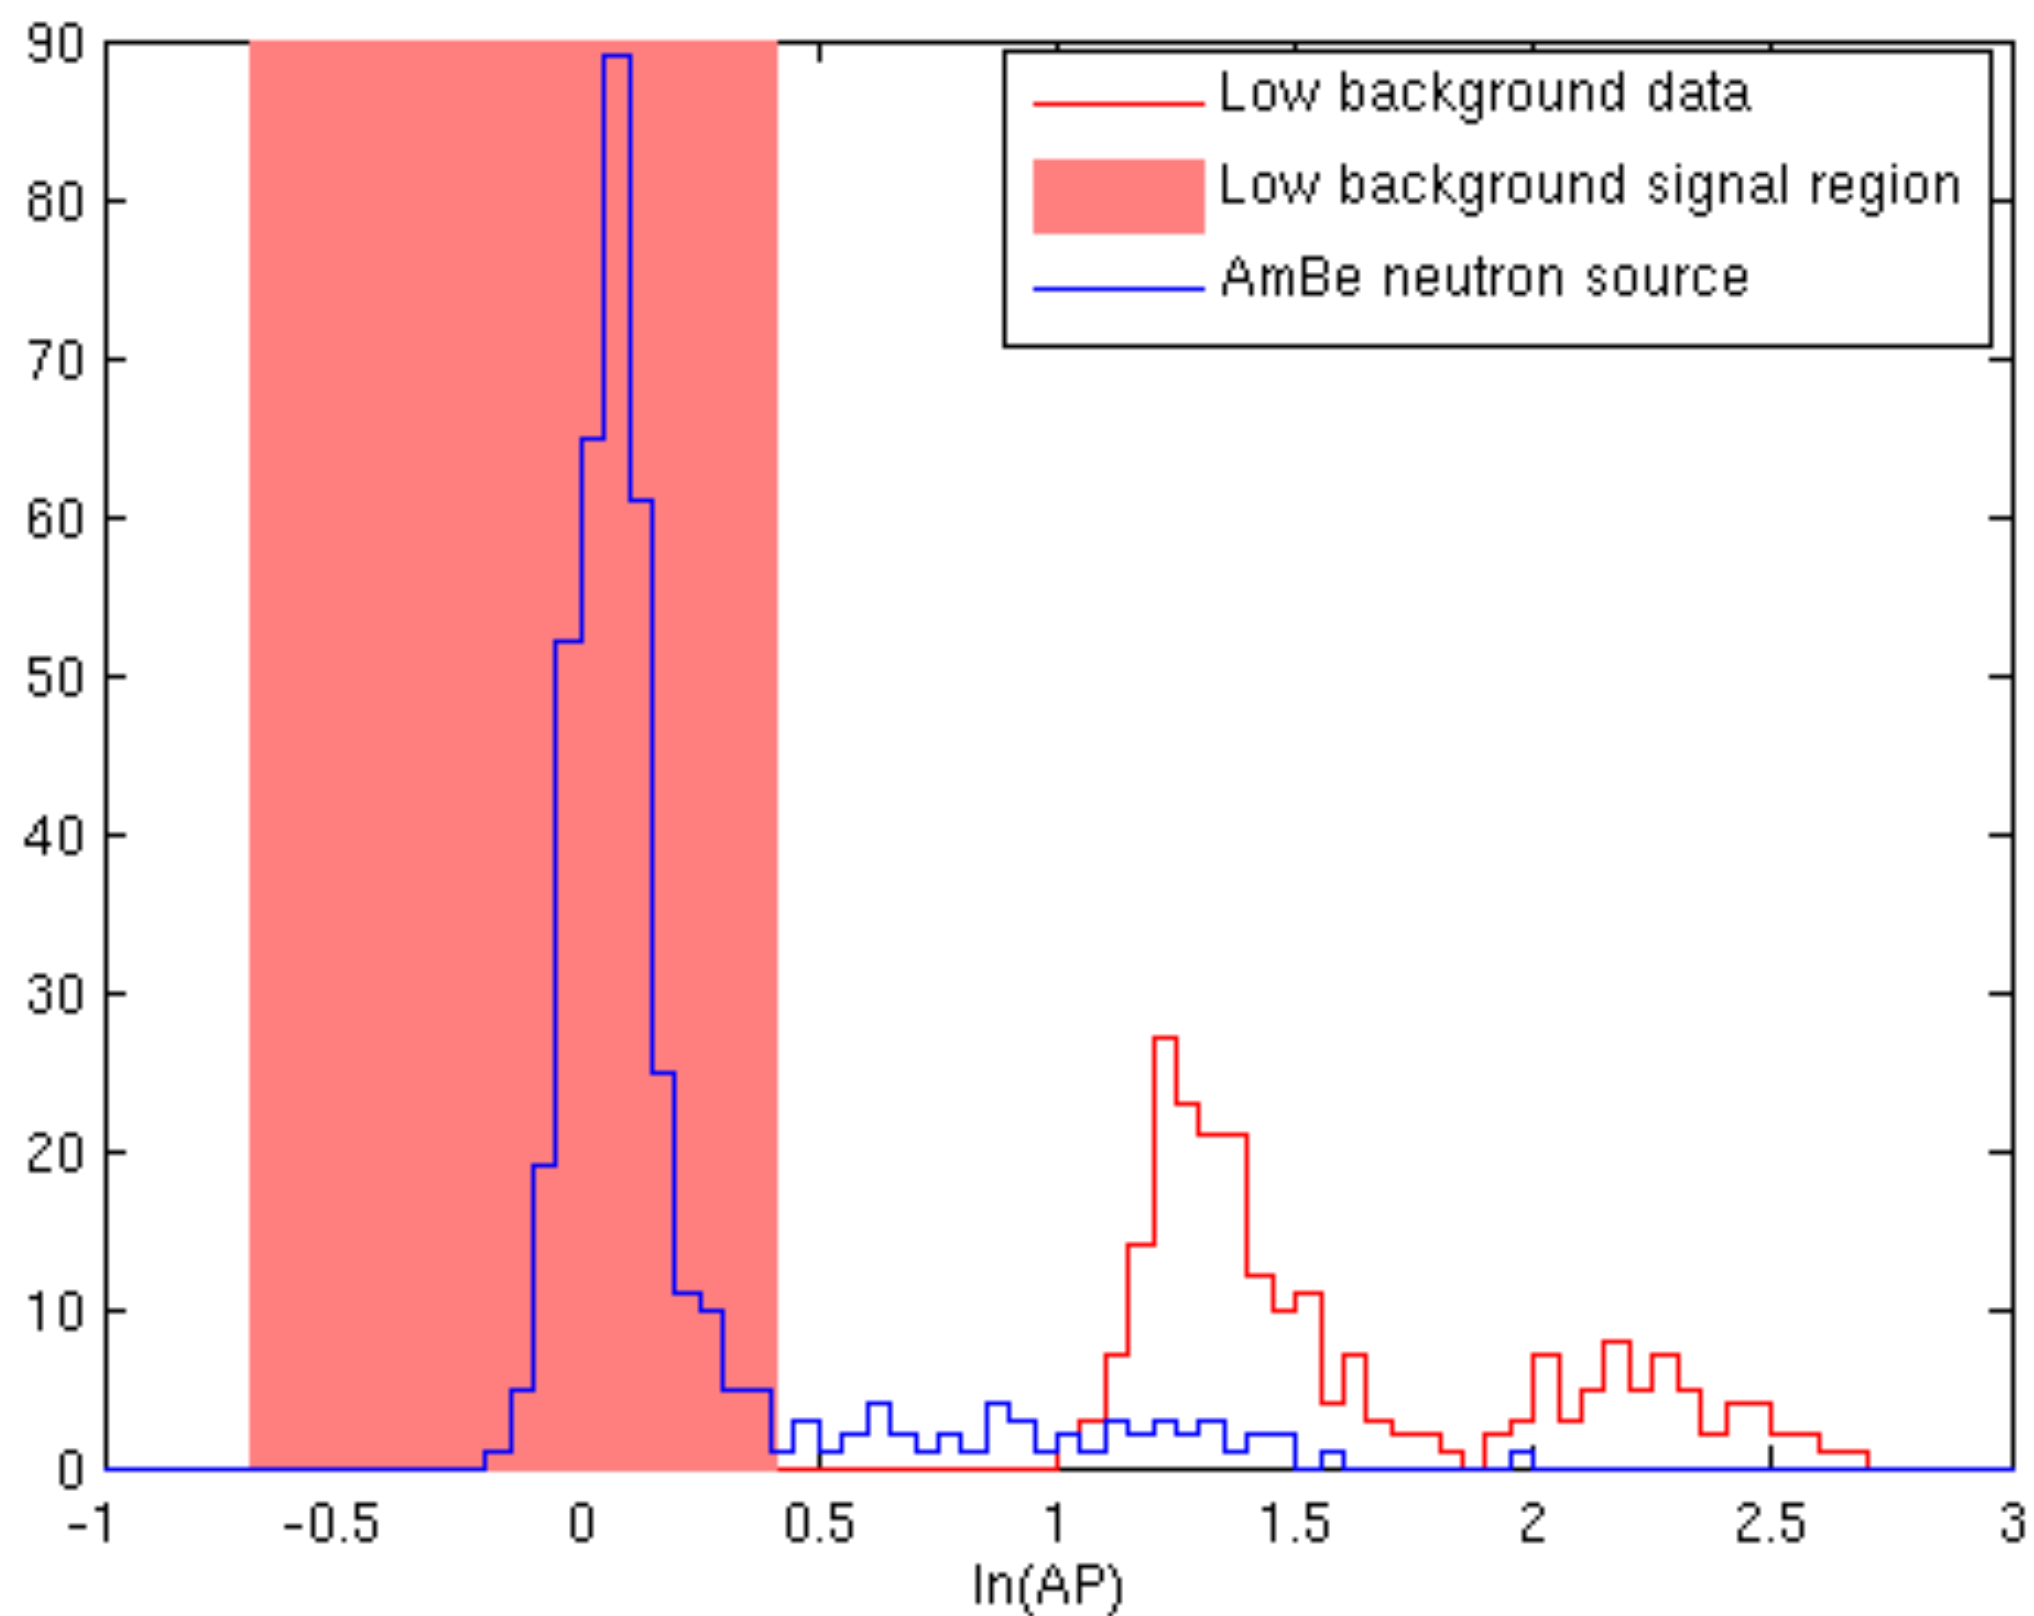

Helium nucleus
(~5 MeV)

PICO_alphas

- > 99.4% rejections of alphas

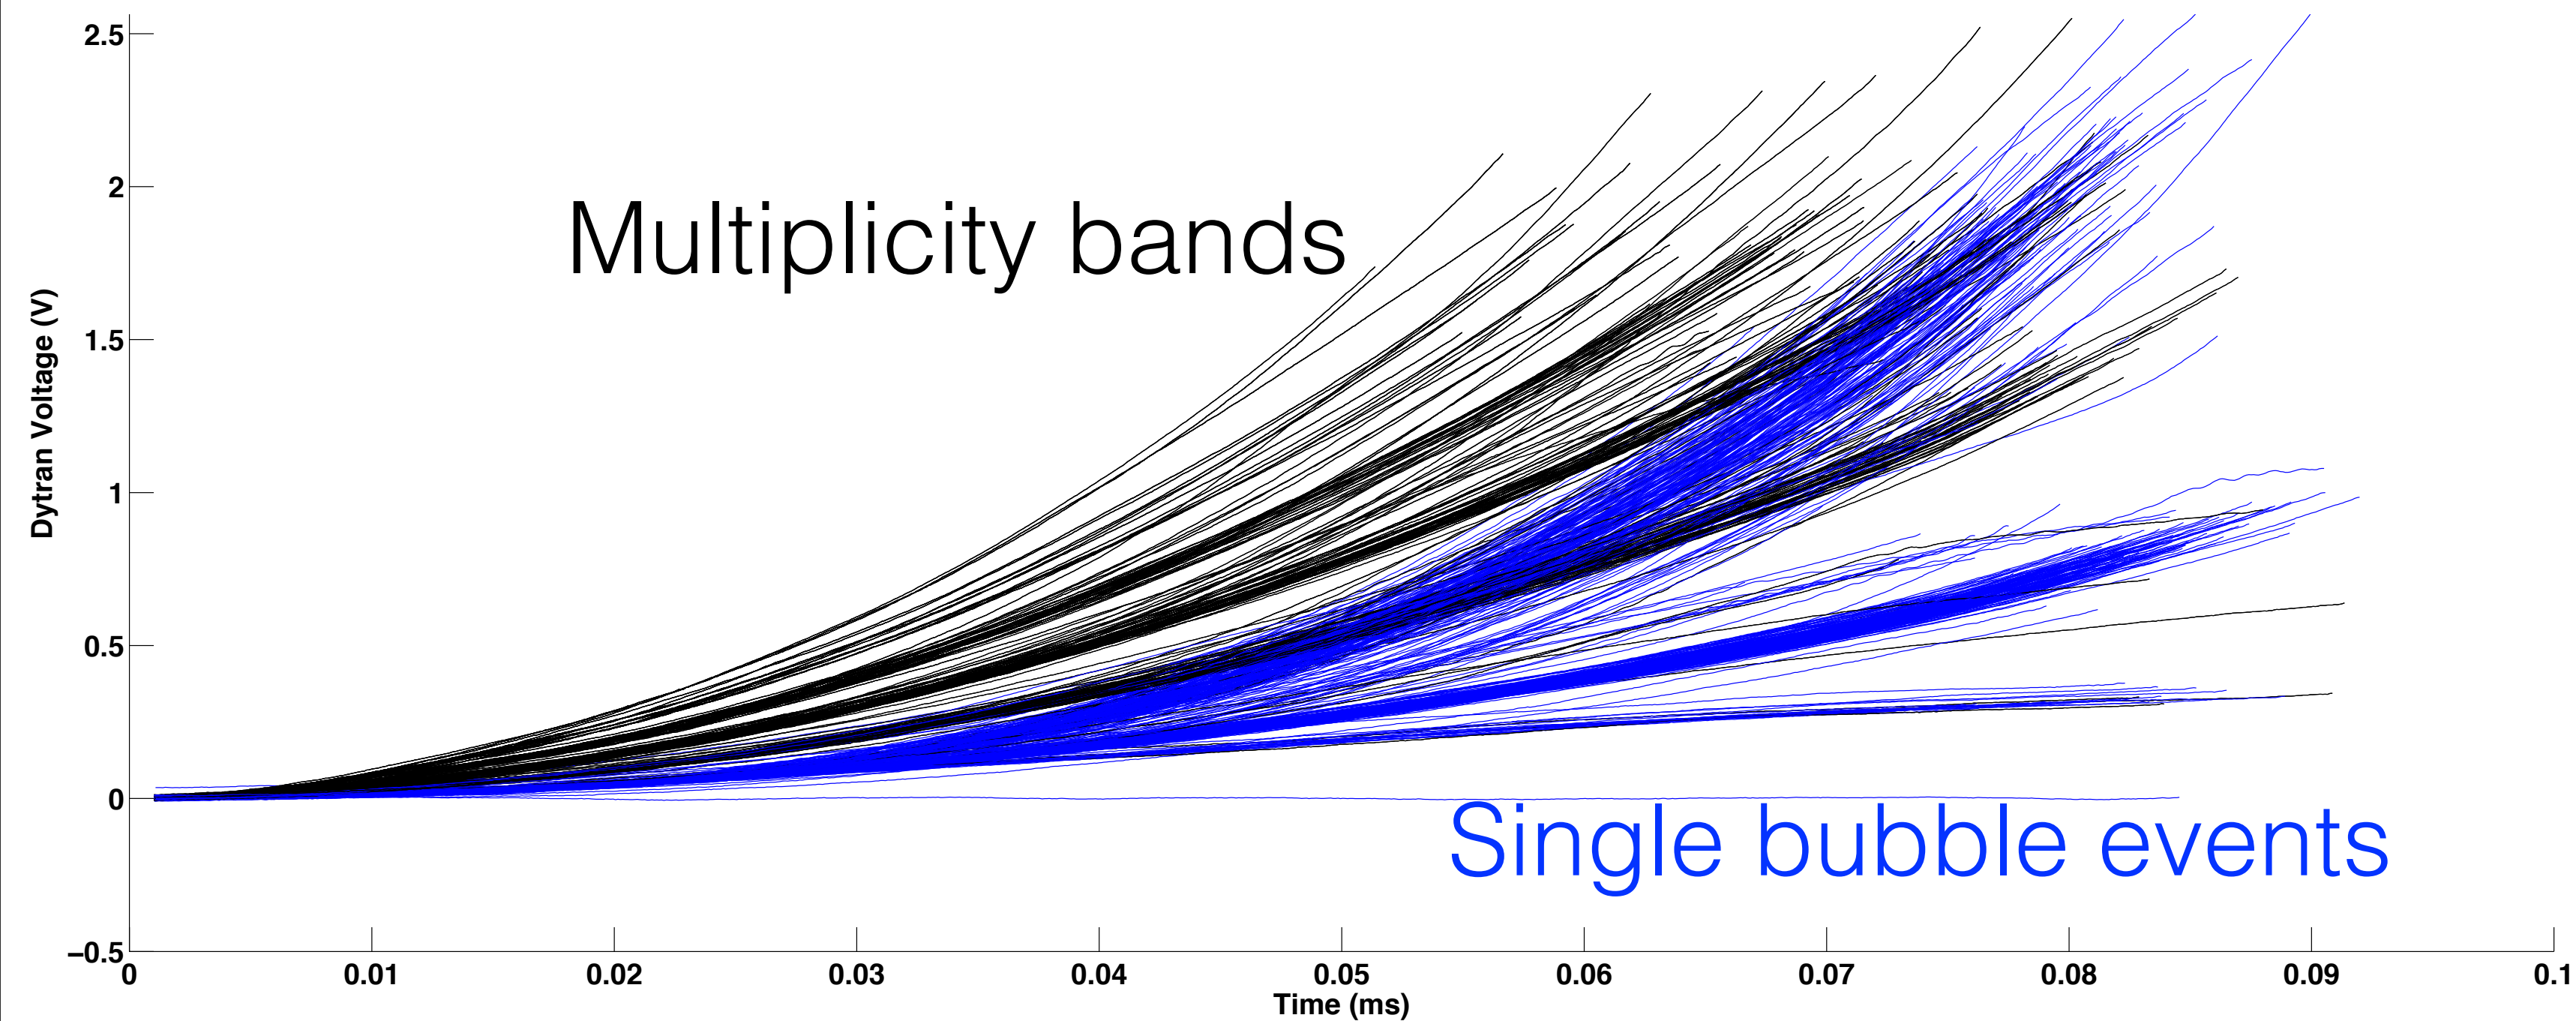

- Timing of high AP events consistent with radon chain alphas.

- Separate peaks indicate higher energy alphas being louder.

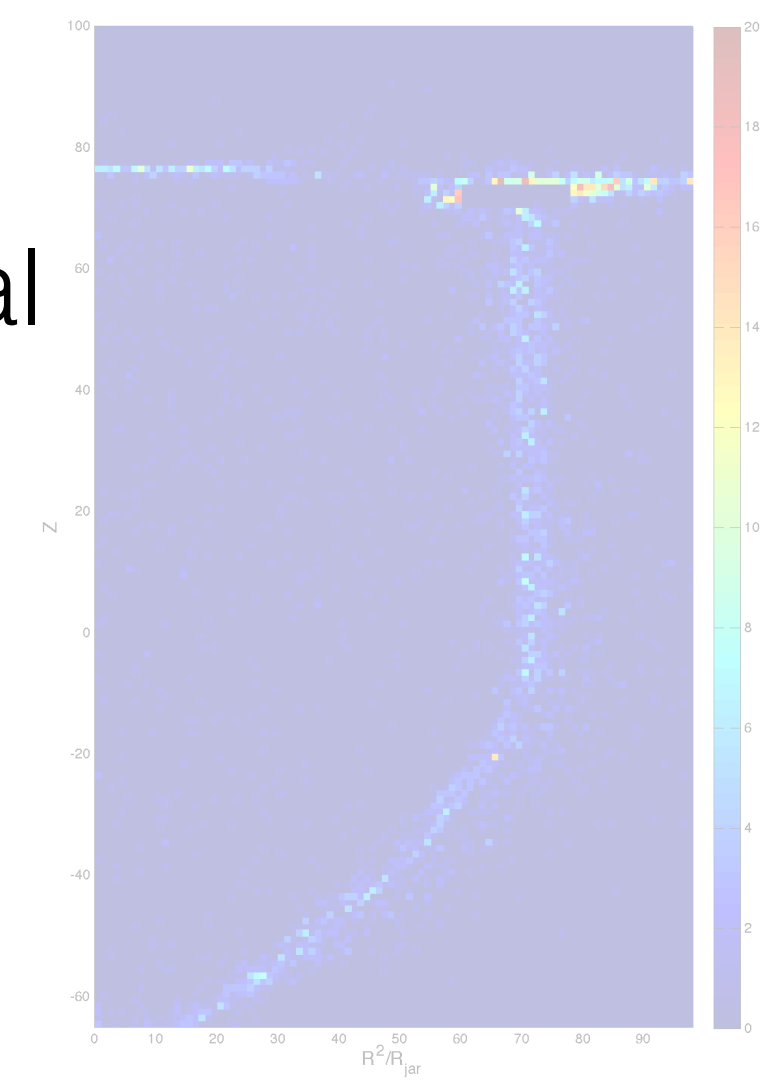

PICO_fiducial volume

- Interfaces provide nucleation sites.
- Pressure change for bubbles on interfaces is different from that in the bulk.
- Multiple bubble events can also be tagged using the pressure change traces

PICO_fiducial volume

- Pressure traces fit with $\mathbf{Ax}^2 + \mathbf{Bx} + C = 0$.

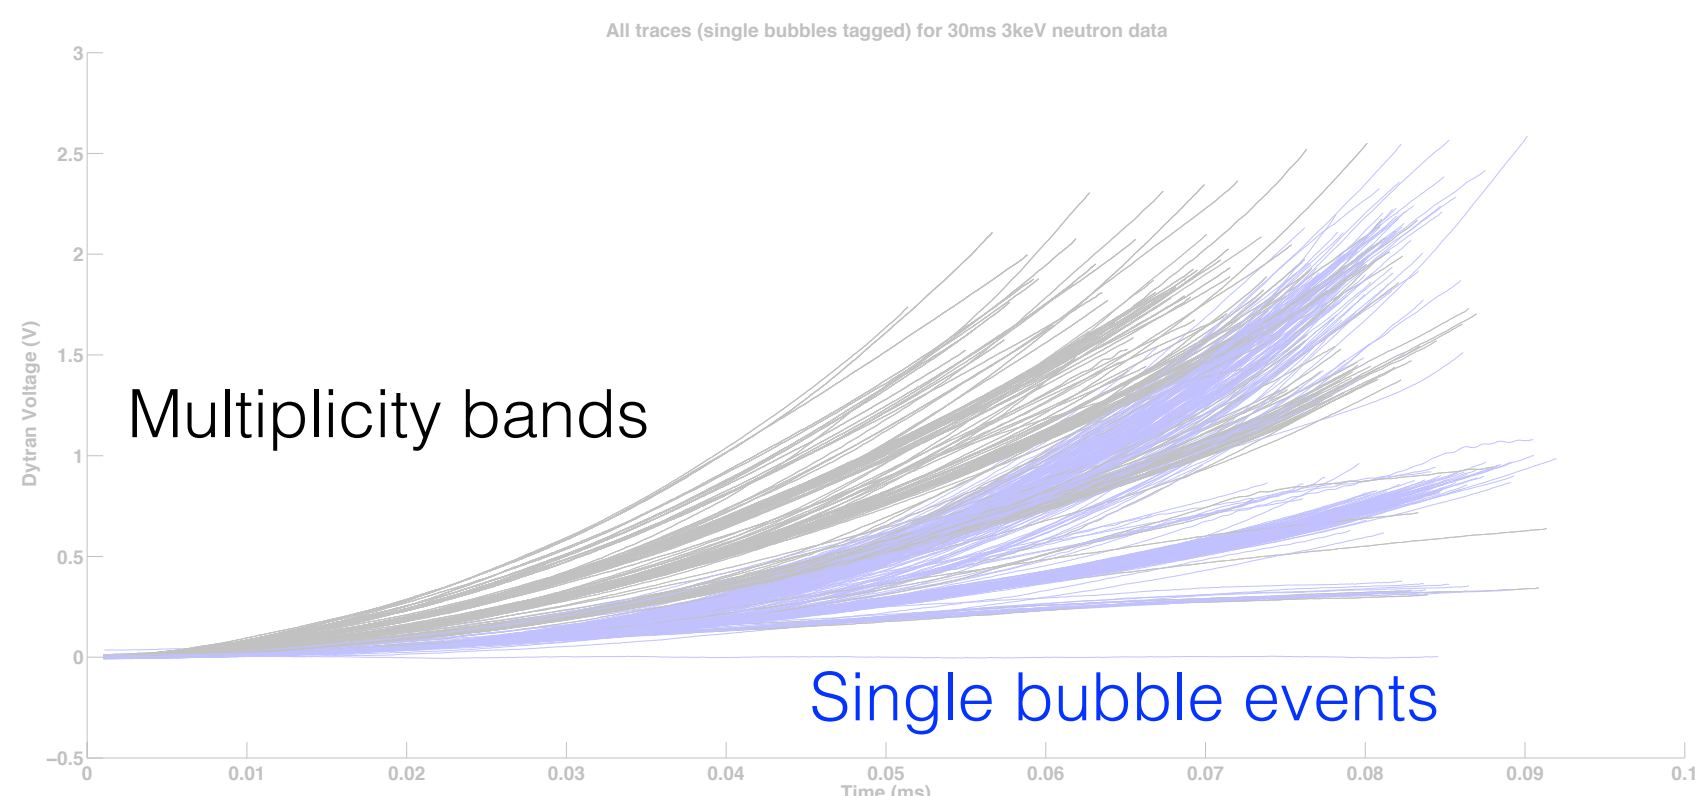

- \mathbf{A} vs GoF used for fiducial information.

- Combination of \mathbf{A} and \mathbf{B} used to calculate \mathbf{A}' which is used for multiplicity.

> 97.5% fiducial volume

> 99.5% acceptance for multiplicity

PICO_projected limits

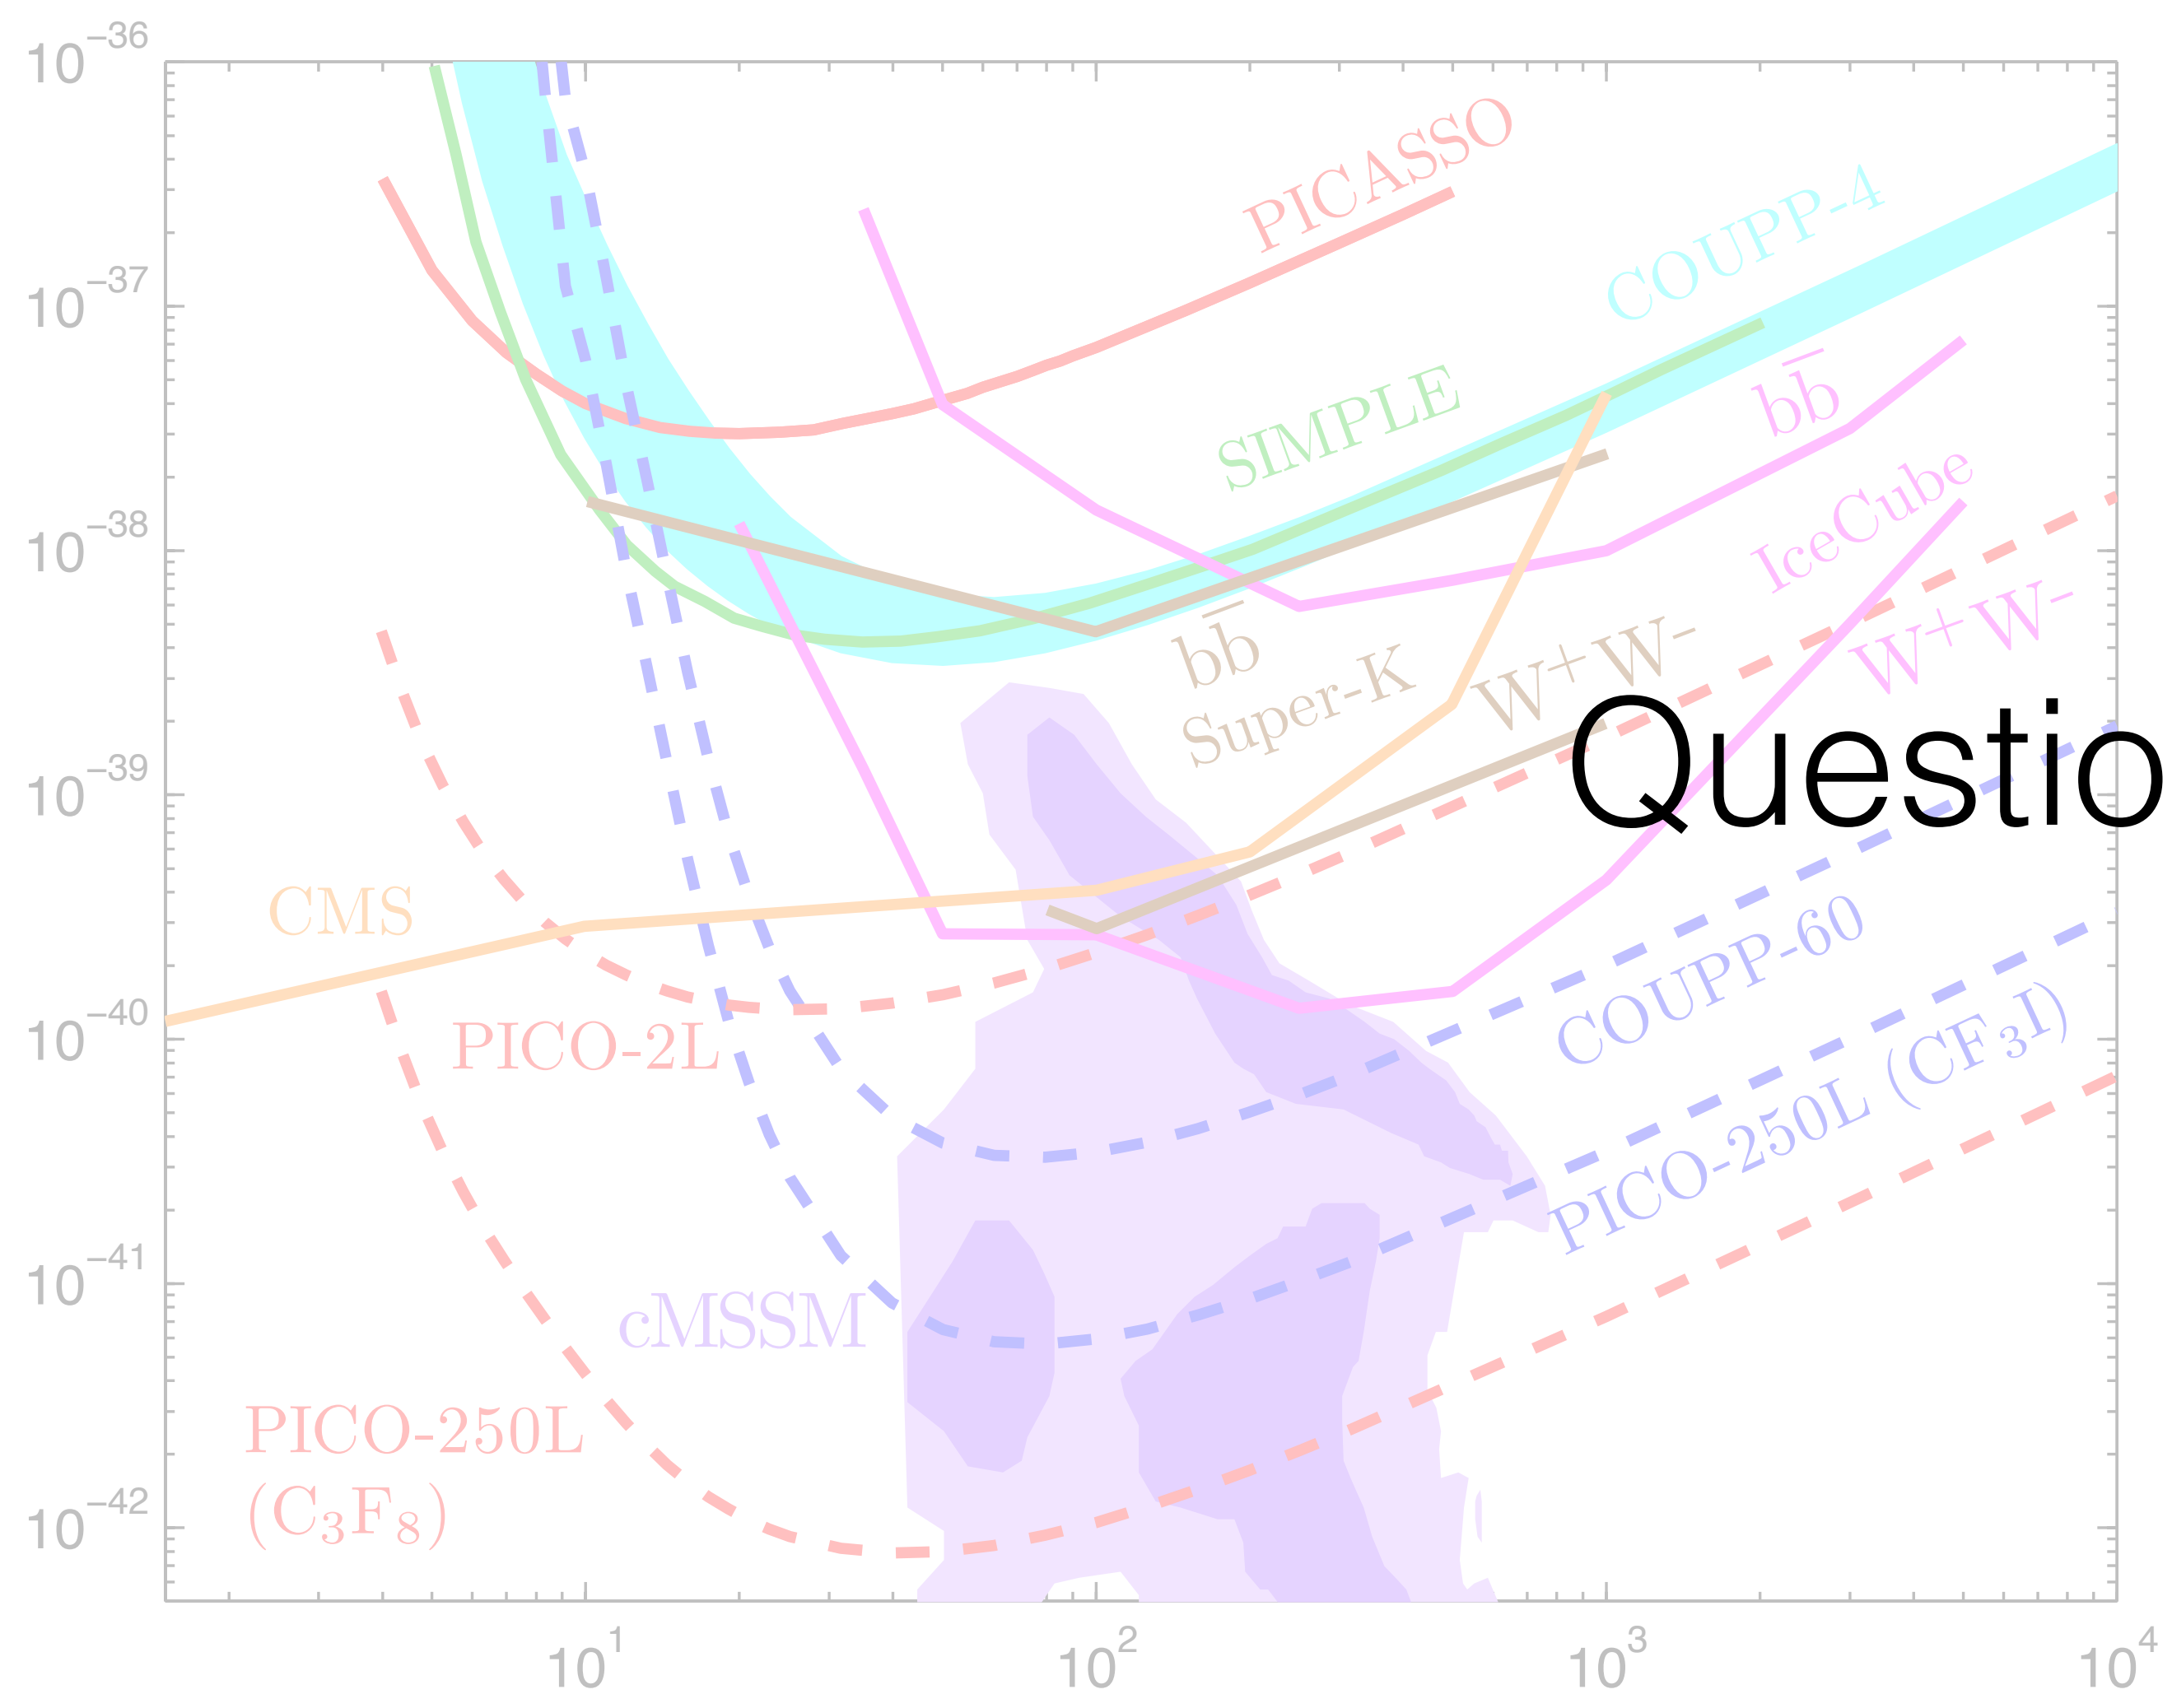

Spin dependent

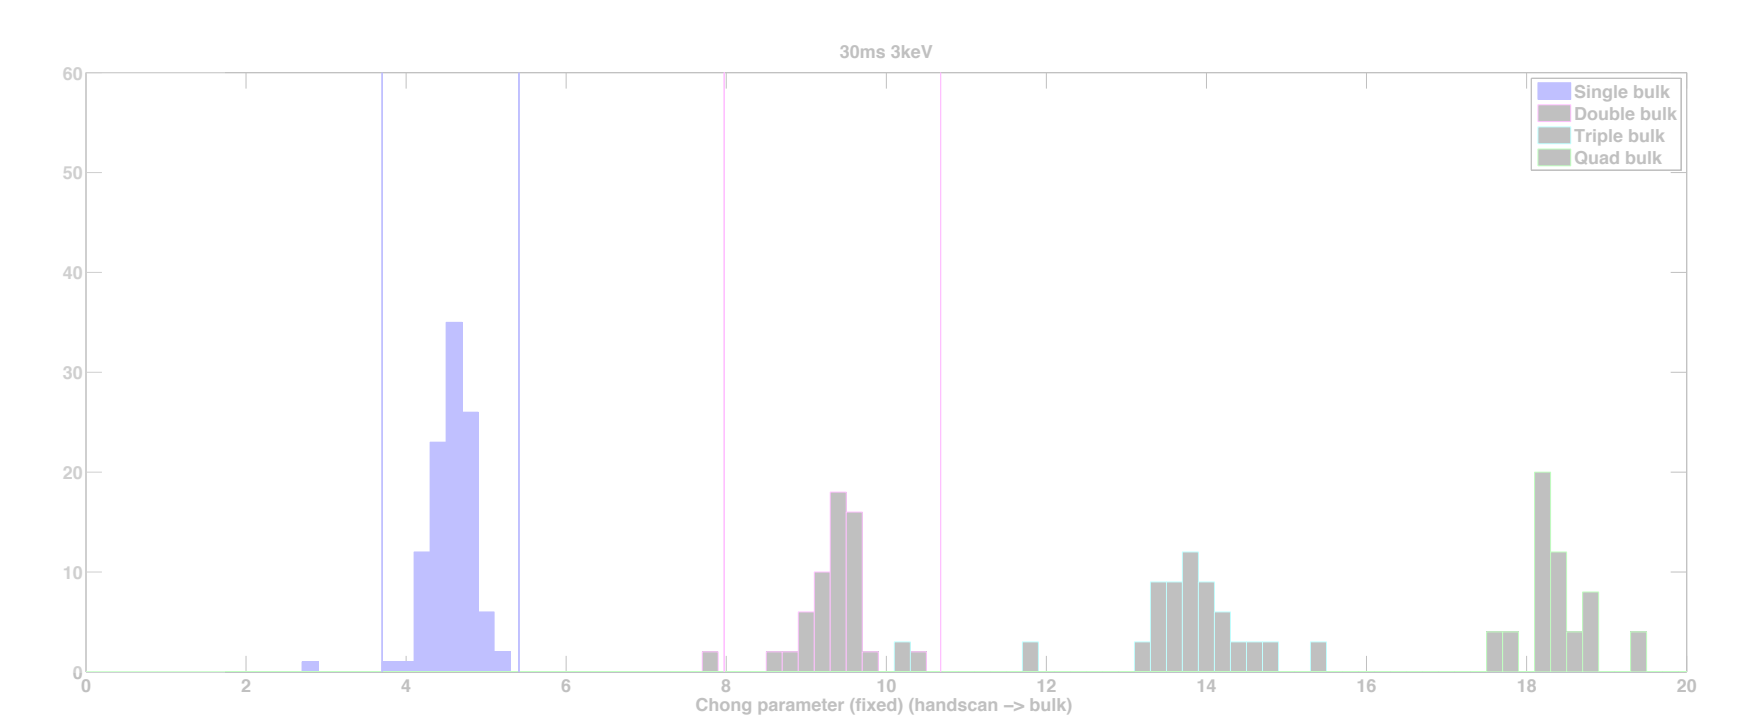

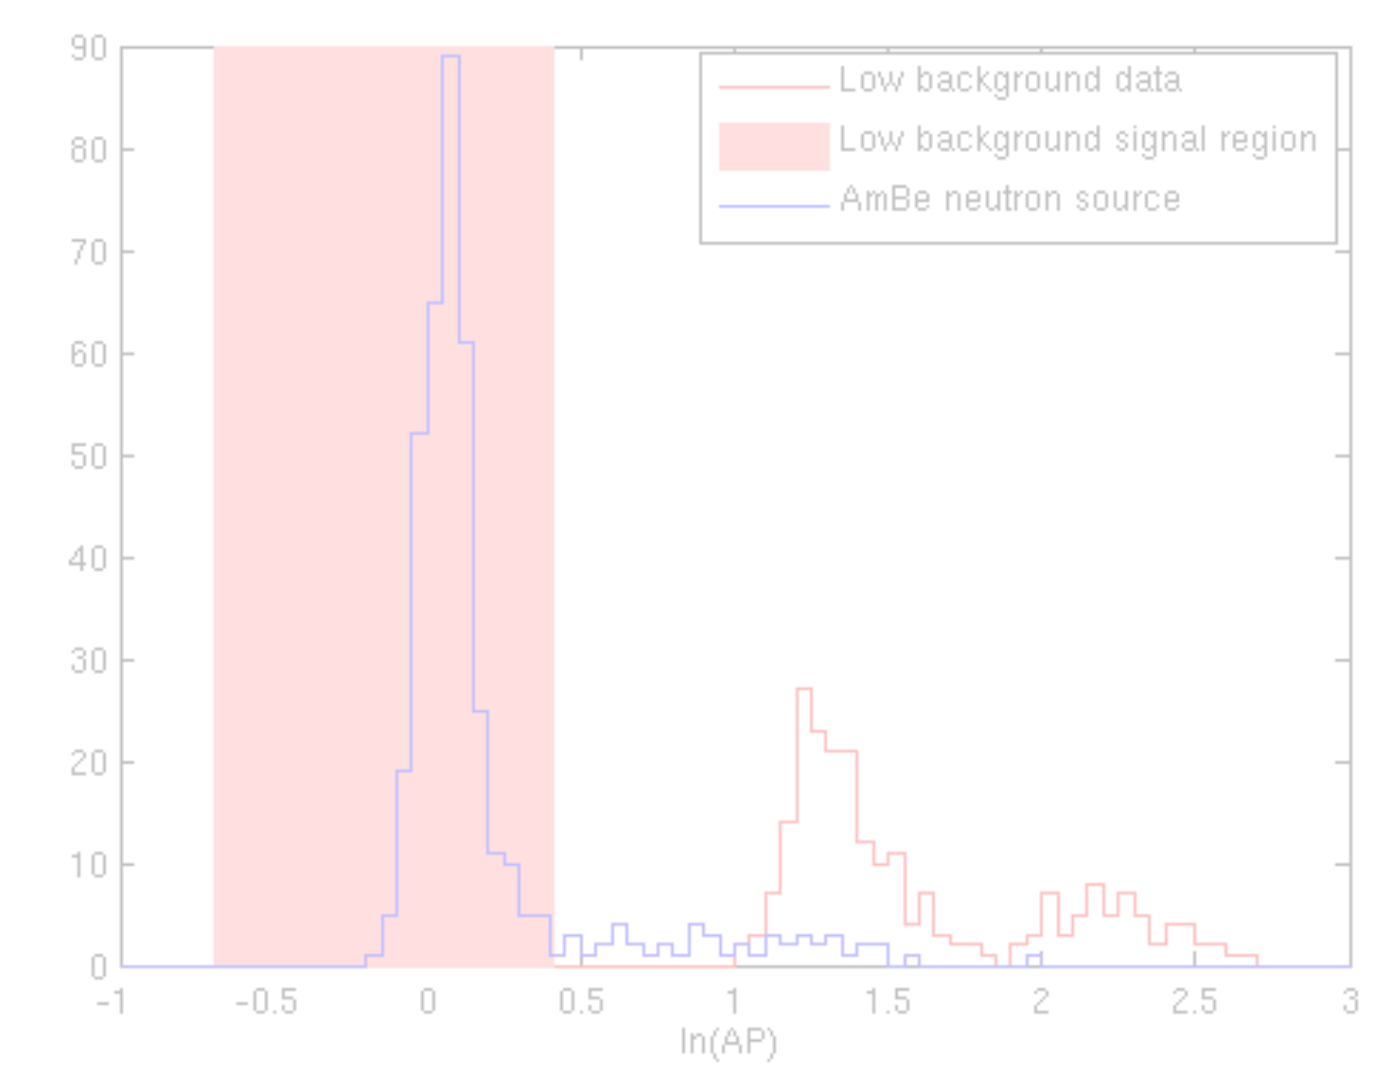

Spin independent

PICO_thanks.

Questions?

PICO_extra slides

PICO_bubble chamber

PICO_sensitivity

$$p_v - p_l = \frac{2\sigma}{r_c}$$

$$E_{th} = 4\pi r_c^2 \left(\sigma - T \frac{\partial \sigma}{\partial T} \right) + \frac{4}{3} \pi r_c^3 \rho_v h$$

surface energy
latent heat

- Energy greater than E_{th} deposited in radius less than r_c is necessary to overcome the surface tension to form a bubble.
- Lower dE/dx results in smaller bubbles that collapse immediately.

- Energy threshold (measure of superheat) can be adjusted to control the sensitivity.
- Superheated liquid can be chosen such that it is **not sensitive to electron recoils** at the working threshold.

C₃F₈ as active fluid

$\sim 10^{-10}$ probability of bubble nucleation per interaction for gammas @ ~ 3 keV threshold.
