Dark matter, DAMA/LIBRA, and ^{40}K [2, 3]

- ▶ Exotic new dark particles may make up bulk of matter in universe.
- ▶ DAMA: ~ 250 kg low-background NaI experiment
- ▶ Since 1997, DAMA claims detection based on annual modulation caused by rotation of Earth around Sun, through particle halo of galaxy:

- ▶ $\frac{\overbrace{\text{modulation amplitude}}^{\text{signal}}}{\underbrace{\text{time-independent amplitude}}_{\text{signal} + \text{background}}} \approx \frac{1}{100}$
- ▶ DAMA controversial:
 - ▶ contradicted by numerous other experiments
 - ▶ no background model [1]
- ▶ Consensus that 3 keV X-rays/Augers from ^{40}K contribute to low-energy DAMA spectrum
- ▶ Contribution is of the order of the amplitude of modulation
- ▶ Precise understanding of ^{40}K is necessary to constrain modulation fraction of signal, and dark matter interpretation [2]
- ▶ ^{40}K is also a background in many other rare-event searches

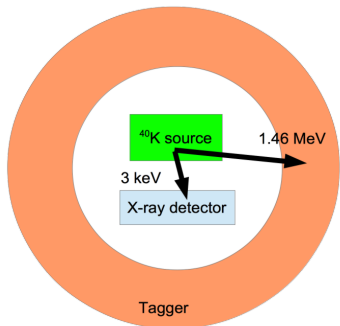

Decays of ^{40}K

- ▶ ^{40}K : naturally occurring; 0.012% abundance
- ▶ $T_{1/2} = 1.2 \times 10^9$ years; main decay is β^- with branching ratio of 90%:

- ▶ Also electron capture (EC):
 - ▶ 3 keV X-rays and Auger electrons from K-shell electron capture: $^{40}\text{K} + e^- \rightarrow ^{40}\text{Ar} + \nu_e$.
 - ▶ Main contribution: **EC*** to excited state of ^{40}Ar , which then decays with $T_{1/2} = 1.6$ ps [4], emitting a 1.46 MeV γ . Branching ratio (BR*) is 10%. Can be tagged by 1.46 MeV γ .
 - ▶ Also contribution that can not be tagged, from direct **EC to ground state**. BR predicted from β^+ decay [5] of ^{40}K to ^{40}Ar as $0.2 \pm 0.1\%$ (theory dependent), and from total decay rate as $0.8 \pm 0.8\%$ (theory independent), but has **never been measured** [2]
 - ▶ EC to ground state would be the only known EC unique third-forbidden transition.

Measuring direct EC with KDK: X-ray detector and tagger

- ▶ Trigger on small inner detector
 - ▶ Low threshold (~ 1 keV) and high efficiency to detect 3 keV X-rays (and Augers?)
 - ▶ Transparent to $E \gtrsim 10$ keV to reduce scattering, background
- ▶ Surround with 4π veto to tag 1.46 MeV γ with high efficiency (bonus if threshold low enough to measure 511 keV γ as cross check of BR_{EC} estimation from BR_{β^+}).
 - ▶ For a signal-to-noise of 1, need an efficiency of 98%
 - ▶ 98% absorption efficiency of 1.46 MeV γ requires 22 cm of NaI (or 77 cm of LAB, or 59 cm of LAr)
- ▶ Compare tagged to untagged triggers to determine ratio of EC to EC*.

Modular Total Absorption Spectrometer (MTAS) tagger [6]

- ▶ At Oak Ridge (ORNL), surface site
- ▶ Made up of 19 NaI(Tl) modules, ≈ 55 kg each, ~ 1 ton total
- ▶ Central tunnel (≈ 6.5 cm diam):
source & X-ray detector go here
- ▶ Efficiency for tagging 1.46 MeV gammas from center is 98–99% (SNR: 1–2)

FIG. 3. The efficiencies of MTAS to detect single γ -ray transition are compared to GEANT4 simulations.

- ▶ BG rate ≤ 1.46 MeV ≈ 240 Hz per module (total ≈ 2.8 kHz \Rightarrow probability one of these events arrives in random $1 \mu\text{s}$ window is 2.8×10^{-3})
- ▶ 0.1% error on efficiency leads to 10% error on branching ratio \Rightarrow more calibrations needed to improve precision

MTAS and X-ray detector at ORNL

MTAS

Vacuum insert with X-ray detector slides into beam pipe

Material minimized around source to avoid γ scattering

X-ray detector (cf M. Stukel's talk M4-3)

- ▶ Large-area avalanche photodiode (APD) chosen for large area, low cost, rather than resolution ($\sigma \approx 7\% @ 6 \text{ keV}$)
- ▶ Device: RMD 1315, 1 cm^2
- ▶ $\approx 1 \text{ keV}$ threshold when cooled to -25° C with water/glycol mix
- ▶ $\approx 1 \text{ mm}$ to sources of standard geometry

Calibrating tagging efficiency with ^{54}Mn (cf P. Squillari POS-38)

Overwhelmingly decays by EC*

Data: ≈ 1 week, $\gtrsim 10^6$ events

$E_X = 5.5$ keV (also 4–6 keV Augers), $E_\gamma = 835$ keV
Standard geometry source

PRELIMINARY estimation
indicates efficiency is
 $(98.89 \pm 0.01)\%$
stat

Also using ^{65}Zn ($EC/EC^* \approx 1$,
 $E_X = 8$ keV, $E_\gamma = 1115$ keV),
and Monte Carlos to extrapolate
to $E_\gamma = 1.46$ MeV.

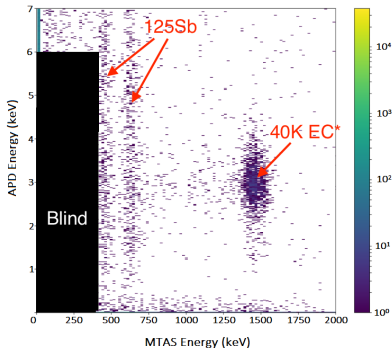

Preparing ^{40}K source (Y.Liu, ORNL)

Equivalent ^{40}K content

- ▶ Driver: $\sim 3 \times 10^4$ untagged 3 keV counts required to provide 10% stat error on ratio of EC/EC* branching ratios
- ▶ Source goals:
 - ▶ 10^{18} ^{40}K nuclei (4×10^3 EC events/day)
 - ▶ Area 1 cm^2 , thickness $< 10 \mu\text{m}$ (to reduced self-absorption and losses of efficiency)
- ▶ First approach: ion beam implantation
 1. Ion source: $\text{KCl} \rightarrow ^{39,40,41}\text{K}^+$ @ 20–40 keV
 2. Magnetic mass separator $\rightarrow ^{40}\text{K}^+$
 3. Implant into C foil (depth a few μm)
- ▶ Expected efficiency 10%; started with natural K, then K enriched to 3% ^{40}K

March 2017 ^{40}K run (EC region blinded) — PRELIM

- ▶ ^{40}K visible in MTAS and APD!
Technique is viable
- ▶ Rate an order of magnitude lower than expected (only $\approx 10^{17}$ ^{40}K atoms)
 - ▶ Measured independently by MTAS, by APD, and by HPGe
 - ▶ Missing ^{40}K found in ion beam line by MTAS
 - ▶ Self-sputtered ^{40}K away?
- ▶ ^{125}Sb contamination in source, probably from ion-beam line
- ▶ Coincident events provide exact shape of signal spectrum to look for regardless of BGs

^{40}K source upgrade options: ^{nat}KCl tests (Y. Liu, ORNL)

Liquid solution evaporation

Thickness hard to control

Thermal deposition

- ▶ Smooth films obtained
- ▶ 30–50% efficiency demonstrated
- ▶ Optimization under way

Conclusions and prospects for KDK

- ▶ Measuring branching ratio of electron capture of ^{40}K to ground state of ^{40}Ar will:
 - ▶ provide better understanding of backgrounds in DAMA claim for discovery of dark matter, and in other dark matter searches
 - ▶ be first observation of EC unique third-forbidden decay
 - ▶ inform nuclear shell models
- ▶ γ -efficiency calibration data obtained
- ▶ **Ability to see ^{40}K coincidences between X-ray detector and γ -tagger has been demonstrated**
- ▶ Analysis progressing: γ -tagging efficiency, backgrounds, ^{40}K
- ▶ Other ongoing work:
 - ▶ stronger, cleaner, ^{40}K source
 - ▶ SDD X-ray detectors with $10\times$ better resolution (MPP and HLL, Munich): insurance against possible β^- BG
 - ▶ KSr_2I_5 scintillator which combines source and X-ray detector (E. Lukosi, UTK)
