Ab initio calculations for exotic nuclei (I)

Wednesday 13 June 2018 13:30 (30 minutes)

One of the recently developed approaches capable of describing both bound and scattering states in light nuclei simultaneously is the No-Core Shell Model with Continuum (NCSMC). This technique represents a state-of-the-art *ab initio* approach and combines the No-Core Shell Model (NCSM) description of short-range correlations with the clustering and scattering properties of the Resonating Group Method. Recent NCSMC calculations of the exotic structure of the ⁹He nucleus will be presented. The properties of this system were investigated by analyzing the $n+^{8}$ He continuum and using chiral interactions as the only input. Our analysis produced an unbound ⁹He nucleus with two resonant states found above the $n+^{8}$ He breakup threshold. In particular, no positive parity ground state was found, indicating the break-up of the parity-inversion mechanism found in the ¹¹Be and ¹⁰Li nuclei of the same N = 7 isotonic chain. Finally, recent calculations for elastic proton-nucleus scattering will be presented too. The differential cross section and the analyzing power for several light target nuclei were computed using a microscopic optical potential constructed from new *ab initio* nonlocal densities obtained within the NCSM framework.
