# SuperCDMS technology

Cryogenic semiconducting crystals (25kg Ge and 3.6kg Si in total), with phonon and ionization sensors

Heat capacity  $\propto T^3$ :  
 $T \sim 10$ 's of mK makes crystal heating, phonon signal easy to see

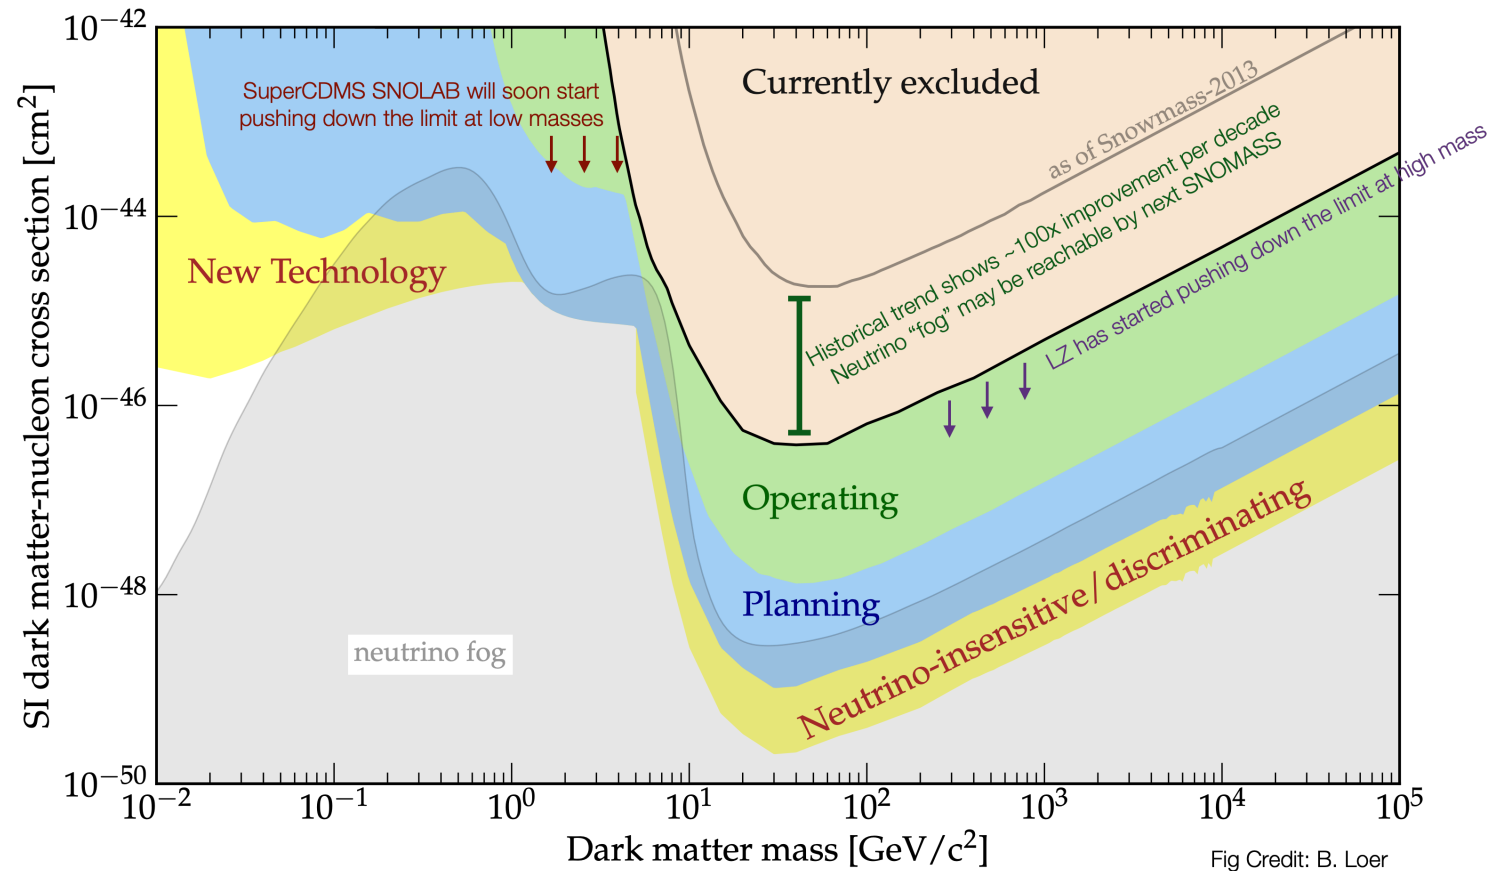

Dark matter interactions create phonon excitations (vibrations) as well as electron/hole pairs in proportion to energy and to yield factor  $Y$ :

$$N_{e/h} = \frac{Y E_r}{\epsilon}$$

$$\begin{aligned} E_{\text{phonon}} &= E_r + N_{e/h} V_{\text{bias}} e \\ &= E_r \left( 1 + Y \frac{V_{\text{bias}} e}{\epsilon} \right) \end{aligned}$$

# SuperCDMS SNOLAB science reach

- Aims to be the world's most sensitive experiment between 0.5-5 GeV/c<sup>2</sup>.
- Both germanium and silicon detectors (two nuclear targets), in two different configurations: 12 HV detectors (lower mass reach) and 12 iZIPs (better background rejection)
- Also sensitive to low energy electron recoils: dark photons, axion-like particles, low mass DM.

# The SuperCDMS SNOLAB Experiment

# First 4-Tower Payload: Strategy to meet Science Goals Complementary Targets and Multiple Functionality

	Germanium	Silicon
HV	Lowest threshold for low mass DM Larger exposure, no $^{32}\text{Si}$ bkgd	Lowest threshold for low mass DM Sensitive to lowest DM masses
iZIP	Nuclear Recoil Discrimination Understand Ge Backgrounds Sensitive to $^8\text{B}$ $\nu$ -scatter	Nuclear Recoil Discrimination Understand Si Backgrounds Sensitive to $^8\text{B}$ $\nu$ -scatter

“Pre-production” towers

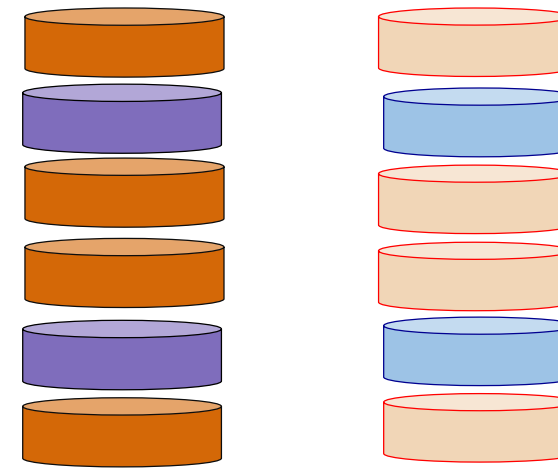

Tower 1 (iZIP)

Tower 2 (HV)

“Production” towers

**Delivered to SNOLAB May 2023**

Tower 3 (HV)

Tower 4 (iZIP)

Production towers  
have less cosmogenic  
exposure

# Installation Progress

Assembled tower at SLAC

Routinely 10-14 people  
underground working on  
installation and commissioning

E-tank in Lab G at FNAL

Shield base assembly

Upper and Lower OVC chambers

Dilution Fridge at SNOLAB

# First detector tower shipment to SNOLAB (cosmogenic activation clock ticking)

Arrival:  
May 12,  
noon EDT

Departure:  
May 9,  
noon PDT

Southern route: avoid  
high elevations

First two towers underground in low radon cleanroom at SNOLAB

# CUTE

- Underground test facility at SNOLAB, capable of operating one SuperCDMS tower or individual detectors
- Operational since 2019
- Platform for doing detector R&D in low background environment, and early science from SuperCDMS while project installation completes
- Once SuperCDMS starts, will be available for testing other cryogenic devices, including quantum computing, new detector designs, etc.

8 PIs, >6 FTE

+ 9 postdocs  
(will ramp  
down to 5  
as MI ends)

+ 14 grad  
students

# Major Canadian responsibilities

- CUTE
  - DAQ
  - SuperCDMS installation
  - Leading role in on-site operations
  - Simulation
  - Data Processing
  - Tier 2 Analysis System
  - Calibration/backgrounds
  - Ionization yield measurements w/ IMPACT, NEXUS test facilities
- } Significant RAP allocation from DRAC

# Papers in the last year

## Ionization yield at low energies

- **Si HVeV** with neutron beam: [arXiv:2303.02196](https://arxiv.org/abs/2303.02196)
- **Ge CDMSlite** with photo-neutron source: [arXiv:2202.07043](https://arxiv.org/abs/2202.07043)

## Snowmass White paper

- Scientific reach of SuperCDMS based technology spanning eV – GeV mass range for upgrades scenarios given 3 incremental background detector improvements [arXiv:2203.08463](https://arxiv.org/abs/2203.08463)

## R&D & DM Searches

- Investigating the sources of low-energy events in a SuperCDMS-HVeV detector [arXiv:2204.08038](https://arxiv.org/abs/2204.08038)

## Instrumentation

- The Level-1 trigger for the SuperCDMS experiment at SNOLAB [arXiv:2204.013002](https://arxiv.org/abs/2204.013002)

# SuperCDMS Detectors & Dark Matter Mass Scales

## Dark Matter Mass Ranges

- High Mass Nuclear Recoil: Full discrimination,  $\gtrsim 5$  GeV
- Low Threshold NR: Limited discrimination,  $\gtrsim 1$  GeV
- HV & 0V Operation: No discrimination,  $\sim 0.3 - 10$  GeV
- Migdal & Brems. Search: no discrimination,  $\sim 0.01 - 10$  GeV
- Electron recoil: HV, no discrimination,  $\sim 0.5$  MeV – 10 GeV
- Absorption (Dark Photons, ALPs): HV, no discrimination,  $\sim 1$  eV – 500 keV (“peak search”)

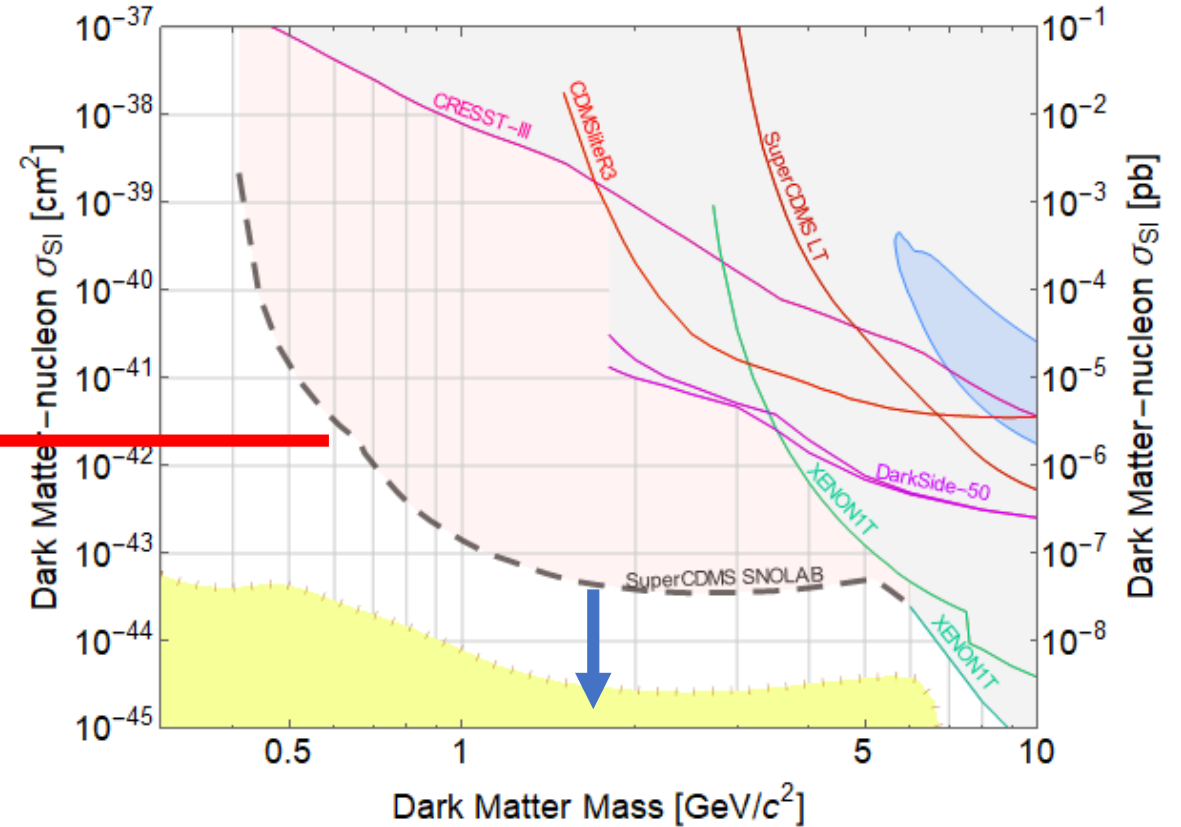

# Upgrade options

- Significant effort by collaboration to understand best upgrade paths

Improve phonon energy resolution to potentially reach  $<0.1$  GeV.  
For example,  $1 \text{ cm}^3$  Si detectors could reach  $\sigma = \sim 10^{-42} \text{ cm}^2$  in this region

See Sunil Golwala's presentation at the SNOLAB Future Projects Workshop 2021 and our SNOWMASS white paper: [arXiv:2203.08463](https://arxiv.org/abs/2203.08463)

Ge iZIP detectors with improved nuclear recoil discrimination could reach the “neutrino fog”

# Conclusions

- 2023-2028 science:
  - Now – late 2024: detector installation and commissioning
  - 2025 – 2028: science running, data analysis  
Best nuclear recoils limits in mass range from  $\sim 0.5\text{-}5 \text{ GeV}/c^2$
  - Limits on very low energy electron recoils: very light dark matter, dark photons, axion-like particles, etc.
  - R&D to understand backgrounds, improve resolution, push down in energy
- Future depends on what is seen in various experiments
  - Any signal from SuperCDMS or other experiments? This is critical issue for deciding on the next step!
  - Collaboration is exploring parallel upgrade paths that lead either to lower mass reach, or better sensitivity in the  $1\text{-}10 \text{ GeV}/c^2$  region. All require significant R&D still, but no show-stoppers seen so far.

# Backups

# Equity and Diversity initiatives

- Instituted SuperCDMS code of conduct
- Ombudsperson program
- Annual anonymous surveys within collaboration about climate, EDI
- New since proposal submission: “SuperCDMS network for women/non-binary or GNC collaborators”. Co-led by Canadian student
- Strong track record: over half of our current postdocs and about half of our graduate students are from traditionally underrepresented groups

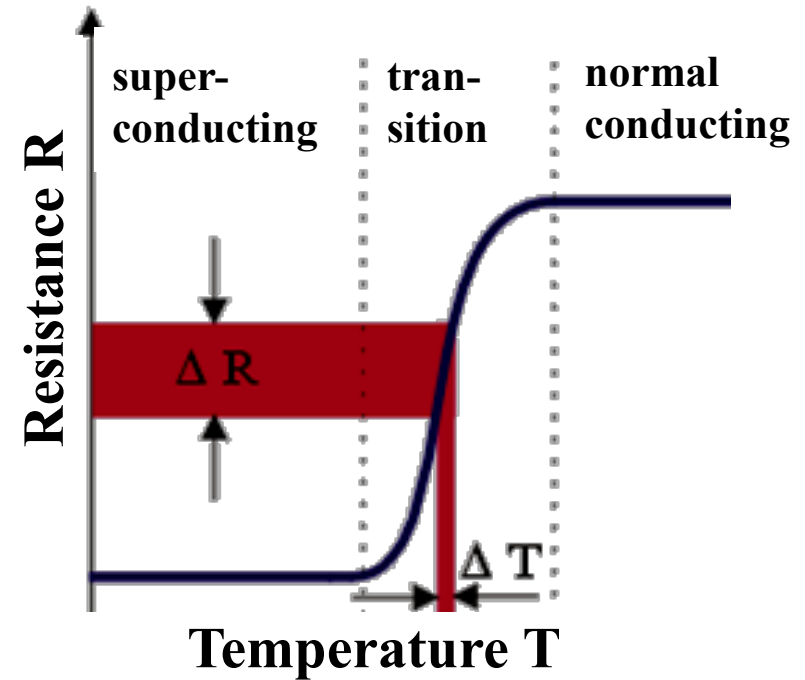

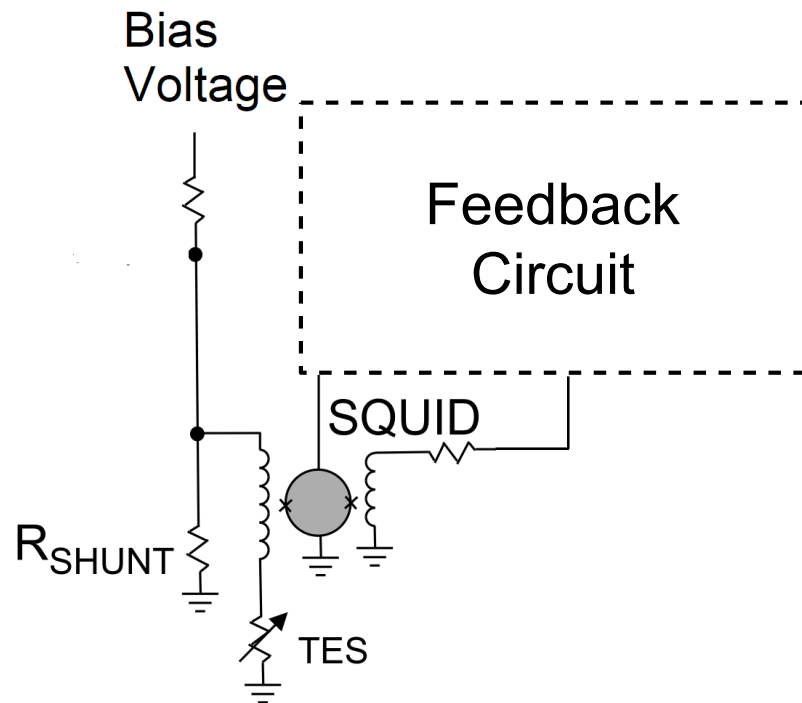

Above solid lines: currently excluded

Dashed lines: projected sensitivities of selected next-generation experiments

# Phonon sensors

Thin Al fins on the crystal surface absorb phonon energy and carry it to a thin tungsten film that is operated in transition between its normal and superconducting state: a **Transition Edge Sensor (TES)**

Changing TES resistance varies magnetic flux through SQUID. Feedback circuit adjusts current through a second inductor to compensate, and we measure that current.

# SuperCDMS at SNOLAB (2023-)

Cryostat:

- Room for 7 towers
- 15mK base temperature

Detector payload:

- 2 HV towers  
(11.2kg Ge, 2.4 kg Si)
- 2 iZIP towers  
(14.0kg Ge, 1.2kg Si)

2km underground in SNOLAB

- Improved radiopurity, cleanliness, and shielding

Low noise electronics with

deadtime-free trigger and new DAQ

# CUTE Installation Photos

# CUTE Installation Photos

# CUTE Installation Photos

# Science Drivers

## Backgrounds:

- In energy range of interest, most important background is cosmogenic  $^3\text{H}$ . Must limit unshielded exposure on surface. Careful assay and selection of materials essential

## Resolution:

- Determines how low in energy threshold (mass) we can go
- Lower base temperature helps!
- Guard against microphonics, RF noise

## Response to small energy deposits

- Optimal filter running in firmware to achieve lowest possible trigger thresholds
- Low energy calibrations to understand detector response to small energy deposits

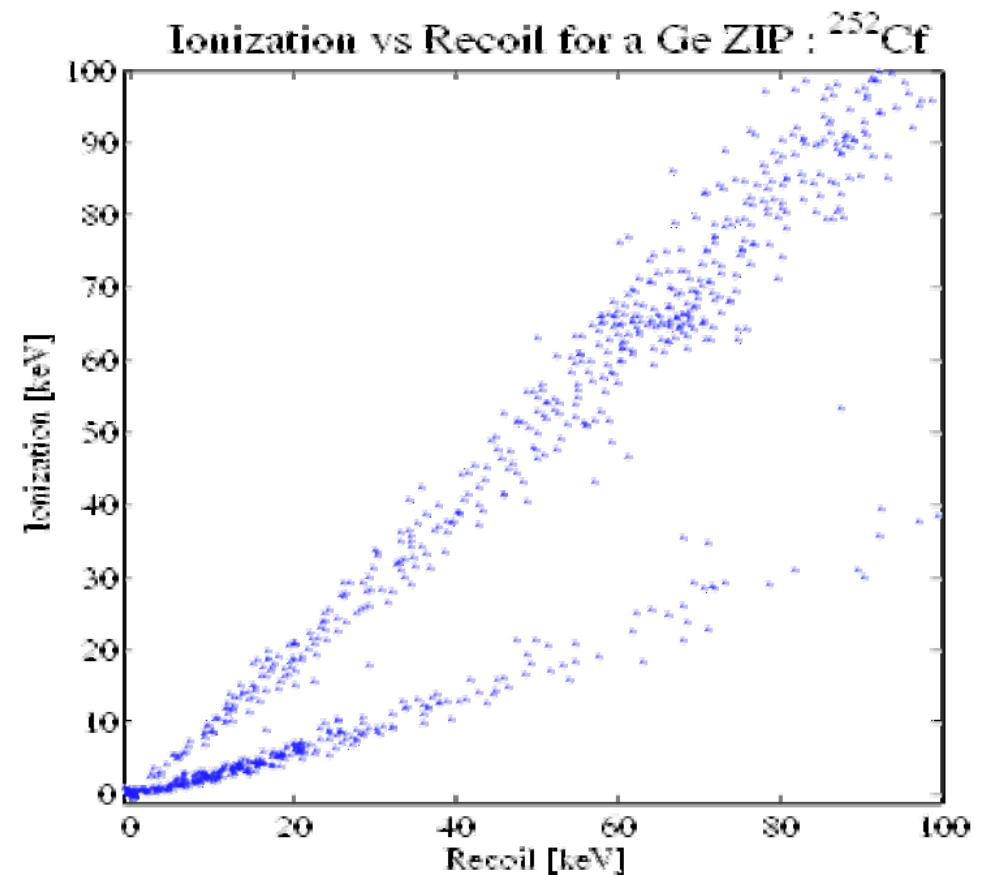

# IZIP Detectors

“Interleaved Z-Sensitive  
Ionization & Phonon Detectors”

Yield for nuclear recoils is lower  
than for electron recoils.

Ratio of ionization to recoil  
energy distinguishes nuclear  
recoils from most backgrounds, which produce electron  
recoils.

This background rejection works best at higher energies  
where the signal-to-noise is highest.

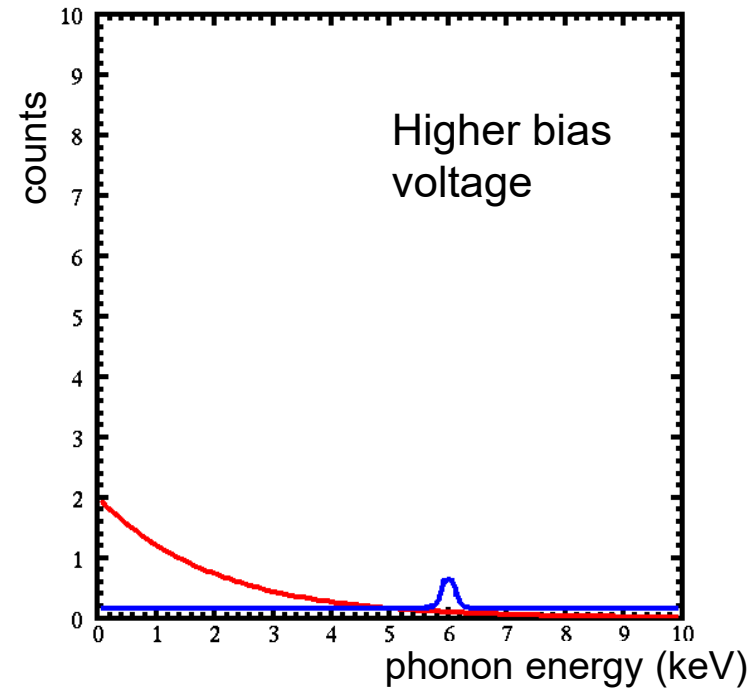

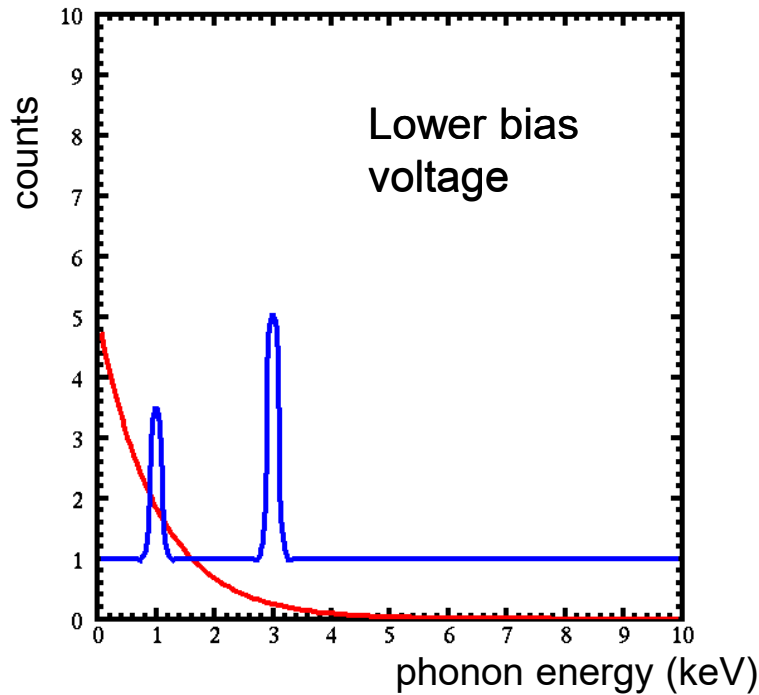

# HV detectors

$$E_{\text{phonon}} = E_r \left( 1 + Y \frac{V_{\text{bias}} e}{\epsilon} \right)$$

**Neganov-Luke amplification:** increasing  $V_{\text{bias}}$  from 4V to ~80V lowers energy threshold, giving sensitivity to much lighter WIMPs

The price: lose electron/nuclear recoil discrimination. But higher  $Y$  for electron recoils pushes them out in energy relative to nuclear recoils, diluting background at low energies.

# Phonon detectors sensitive to single electron/hole excitations

Si prototype detector  
(0.93g)

Clearly count single excitations in phonon signal through Neganov-Luke gain!

Electron recoils will dominantly occur only in peaks, while nuclear recoils, with much higher ratio of direct phonon to ionization yield, will fill in the valleys

$$E_{phonon} = E_r \left( 1 + Y \frac{V_{bias} e}{\epsilon} \right)$$

# Dark photons

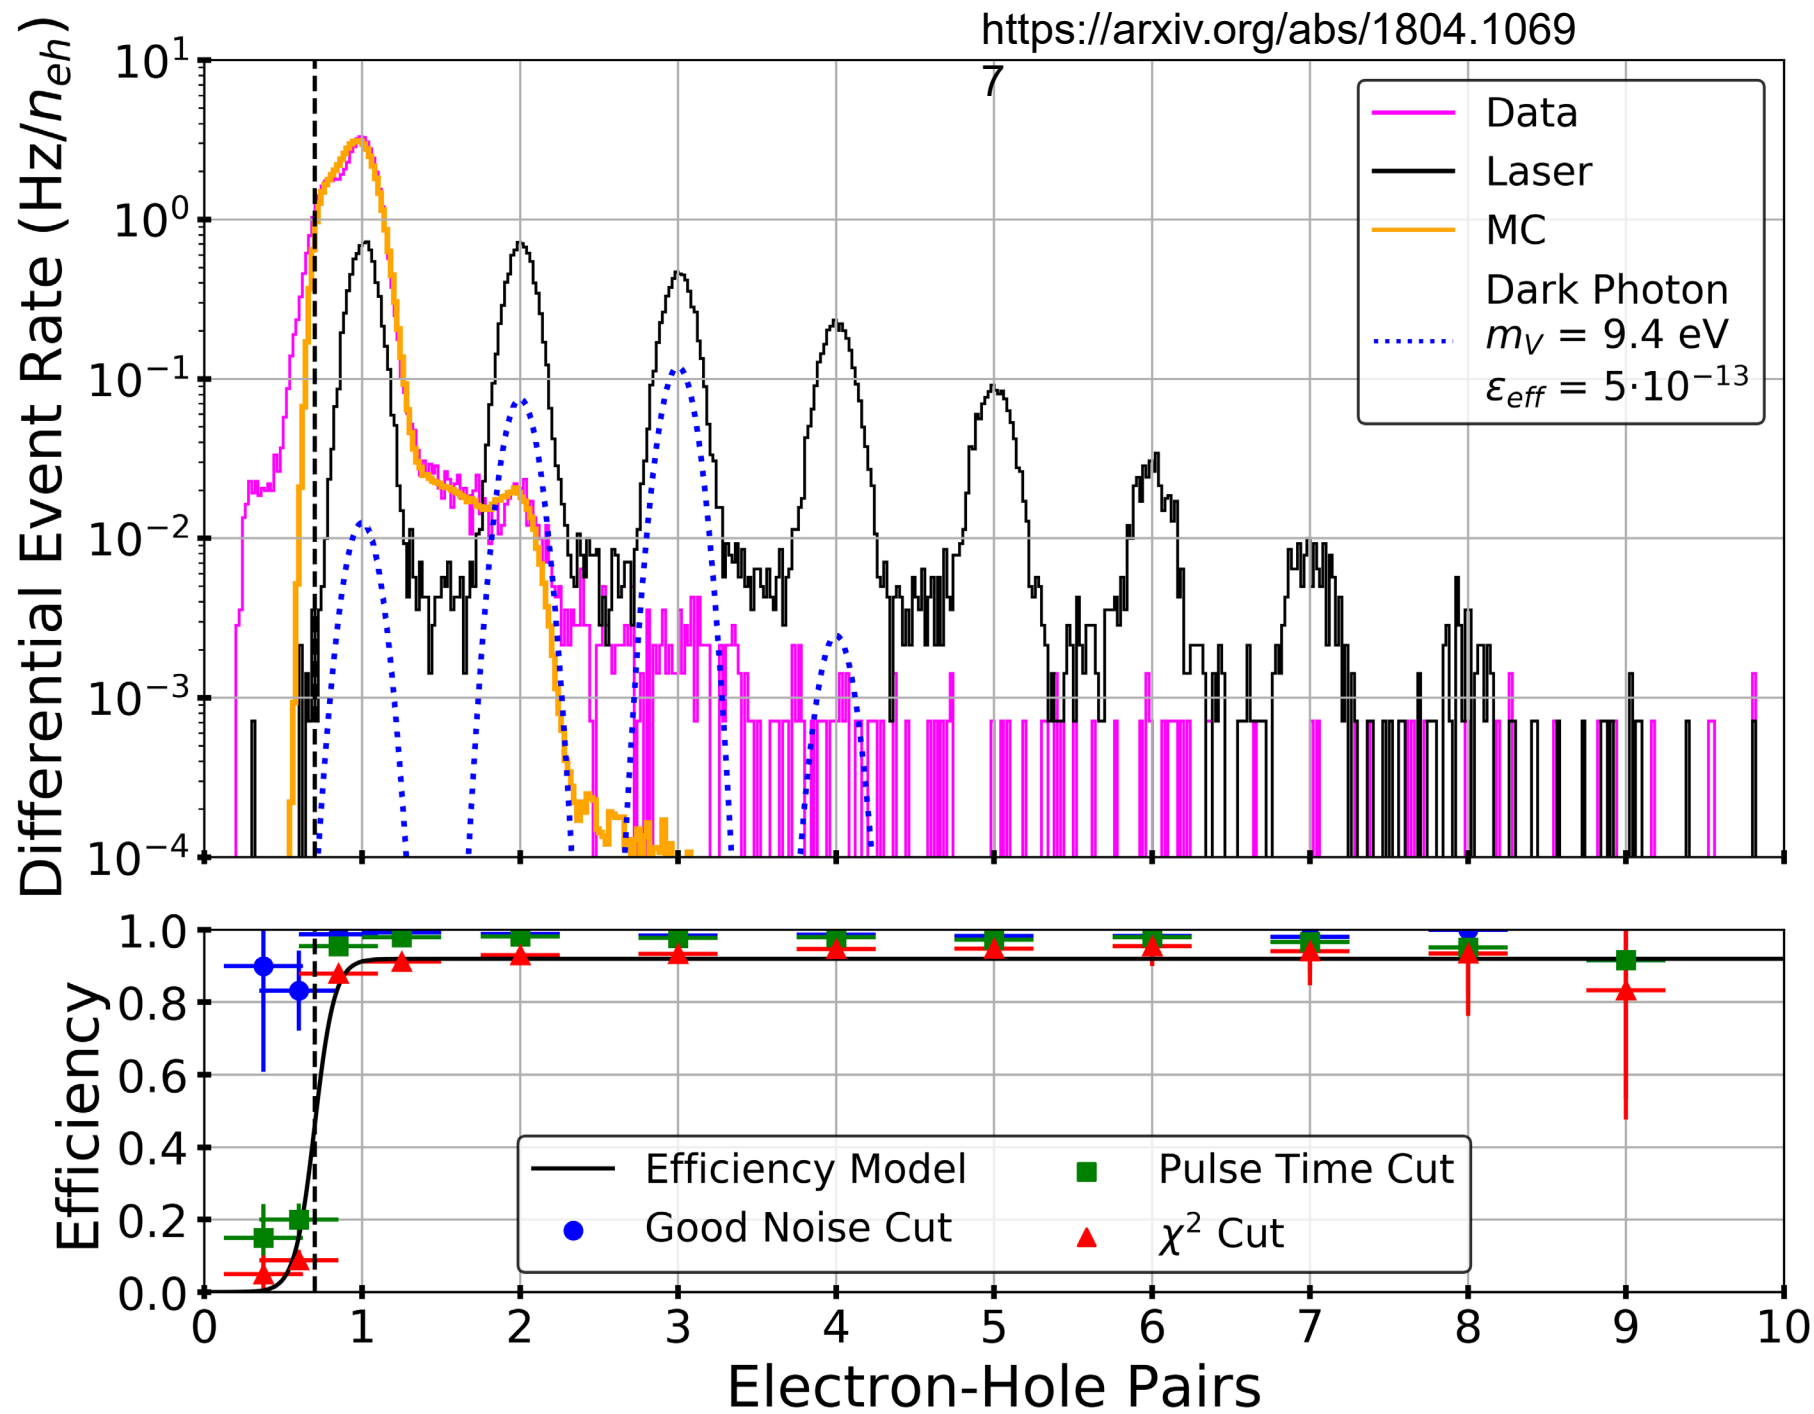

Suppose a hidden sector contains particles with a  $U(1)$  gauge symmetry. The resulting “dark photon” will have the same quantum numbers as a photon. If the gauge symmetry is broken it may be massive.

This massive dark photon can kinetically mix with the SM photon:

A dark photon interacting in our detectors can produce a “dark photoelectric” absorption, resulting in the production of one or more electron/hole pairs. The absorbed energy is the dark photon mass.

Search is sensitive down to masses given by the Si bandgap (few  $eV/c^2$ )!

# Dark photon limits

$$R = V_{Det} \frac{\rho_{DM}}{m_V} \varepsilon_{eff}^2(m_V, \sigma) \sigma_1(m_V)$$

Competitive limits from just 0.49 g·days of exposure from a test device

Mass sensitivity down to just above 1 eV!

# Electron recoil DM

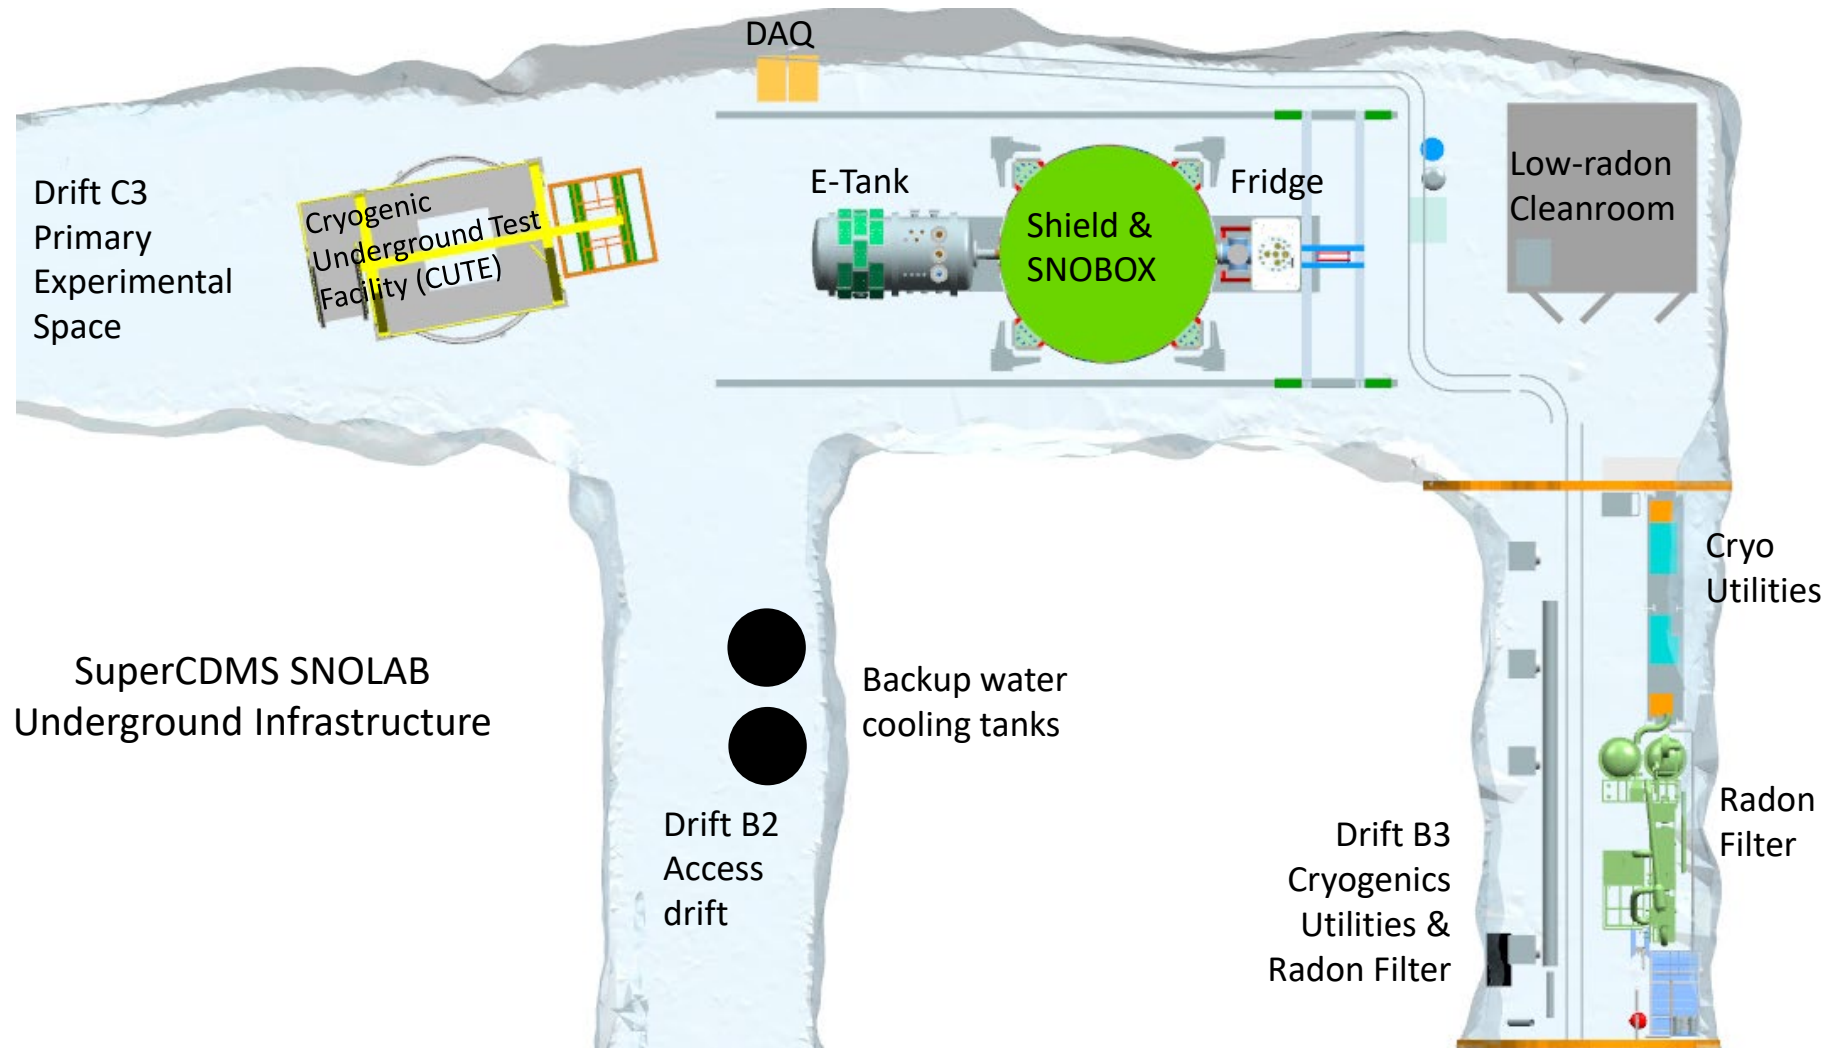

$$\frac{dR}{d(\ln(E_R))} = V_{Det} \frac{\rho_{DM}}{m_\chi} \frac{\rho_{Si}}{2m_{Si}} \bar{\sigma}_e \alpha \frac{m_e^2}{\mu_\chi^2} I_{Crystal}$$

Inelastic electron recoils can excite electrons across Si bandgap, giving us world's best limits on DM interactions with electrons at masses around 1 MeV/c<sup>2</sup> ... from a tiny test device!

# The Facility: SNOLAB Ladder Lab @ 6800 ft level and the SuperCDMS SNOLAB Experiment Layout

# The Facility: Shielding, Fridge, and Electronics

# Nuclear Recoil Calibration at Low Energy

Energy scale calibration with radioactive sources → electron recoils  
But need nuclear recoil energy scale, in particular: ionization efficiency

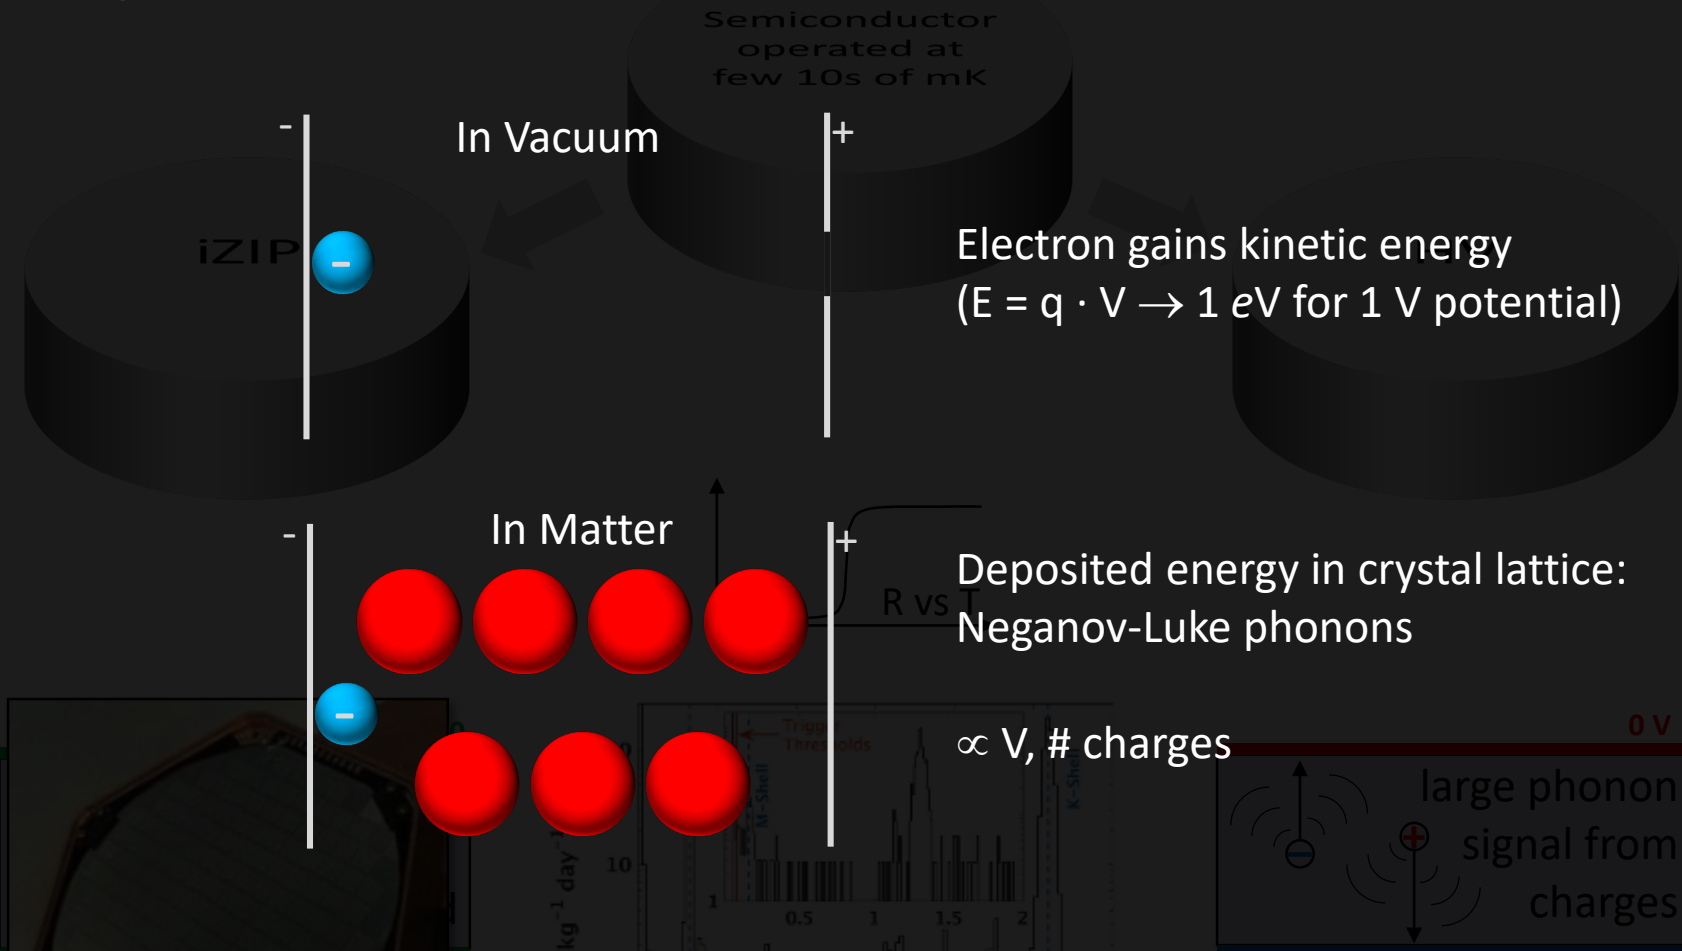

- Use pulsed low-energy neutron beam
- Measure recoils response together with scattered neutrons
- Kinematics fixed, so recoil energy known
- Need small detectors to avoid multiple scatters
- Develop gram-scale detectors with eV-resolution (single eh-pairs)
- Finalizing analysis of first run at TUNL
- Further calibrations planned using Ge / lower energy neutrons

55.7 keV neutrons

# Neganov-Luke Effect

- Luke phonons mix charge and phonon signal  $\rightarrow$  reduced discrimination
- Apply high voltage  $\rightarrow$  large final phonon signal, measures charge!!
- ER much more amplified than NR  $\propto V_{ee}^2$   
 $\rightarrow$  gain in threshold; dilute background from ER

# The SuperCDMS Collaboration

>130 scientists at 28 institutions & 6 Countries, including 3 US national labs and 2 Canadian labs
