ATLAS Collaboration JHEP05(2019)142

Searching for Decades

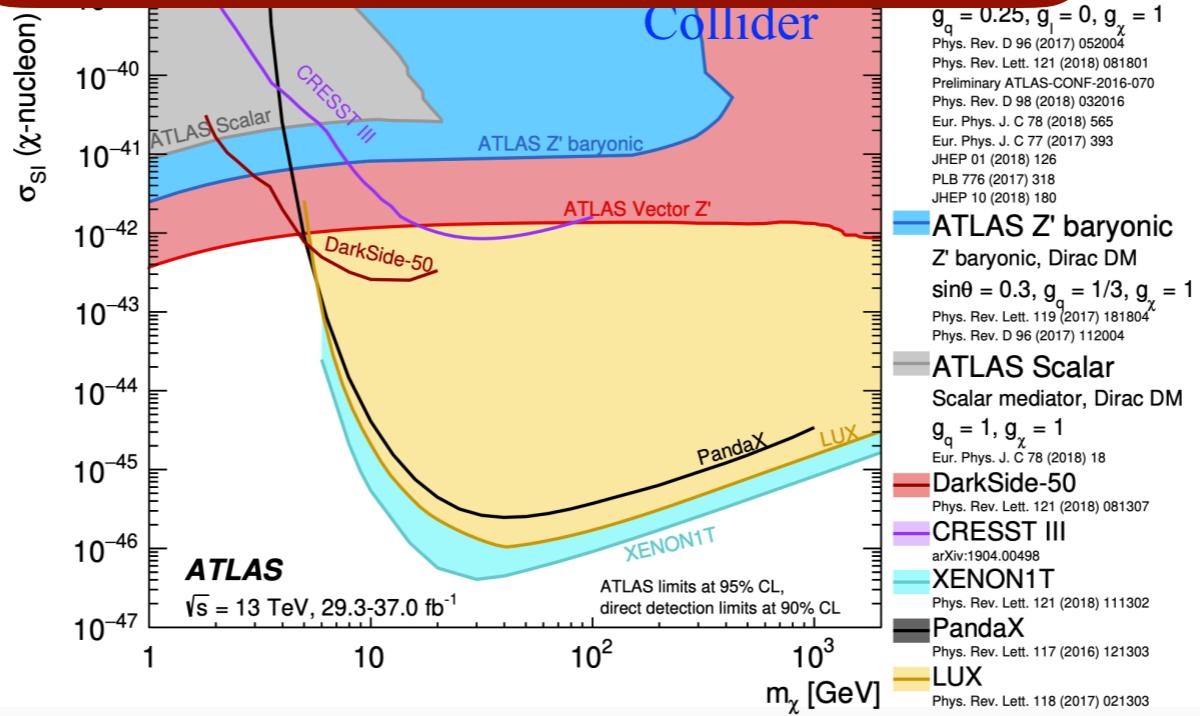

Akerib et al, arXiv: 2203.08084

Heavily constrained

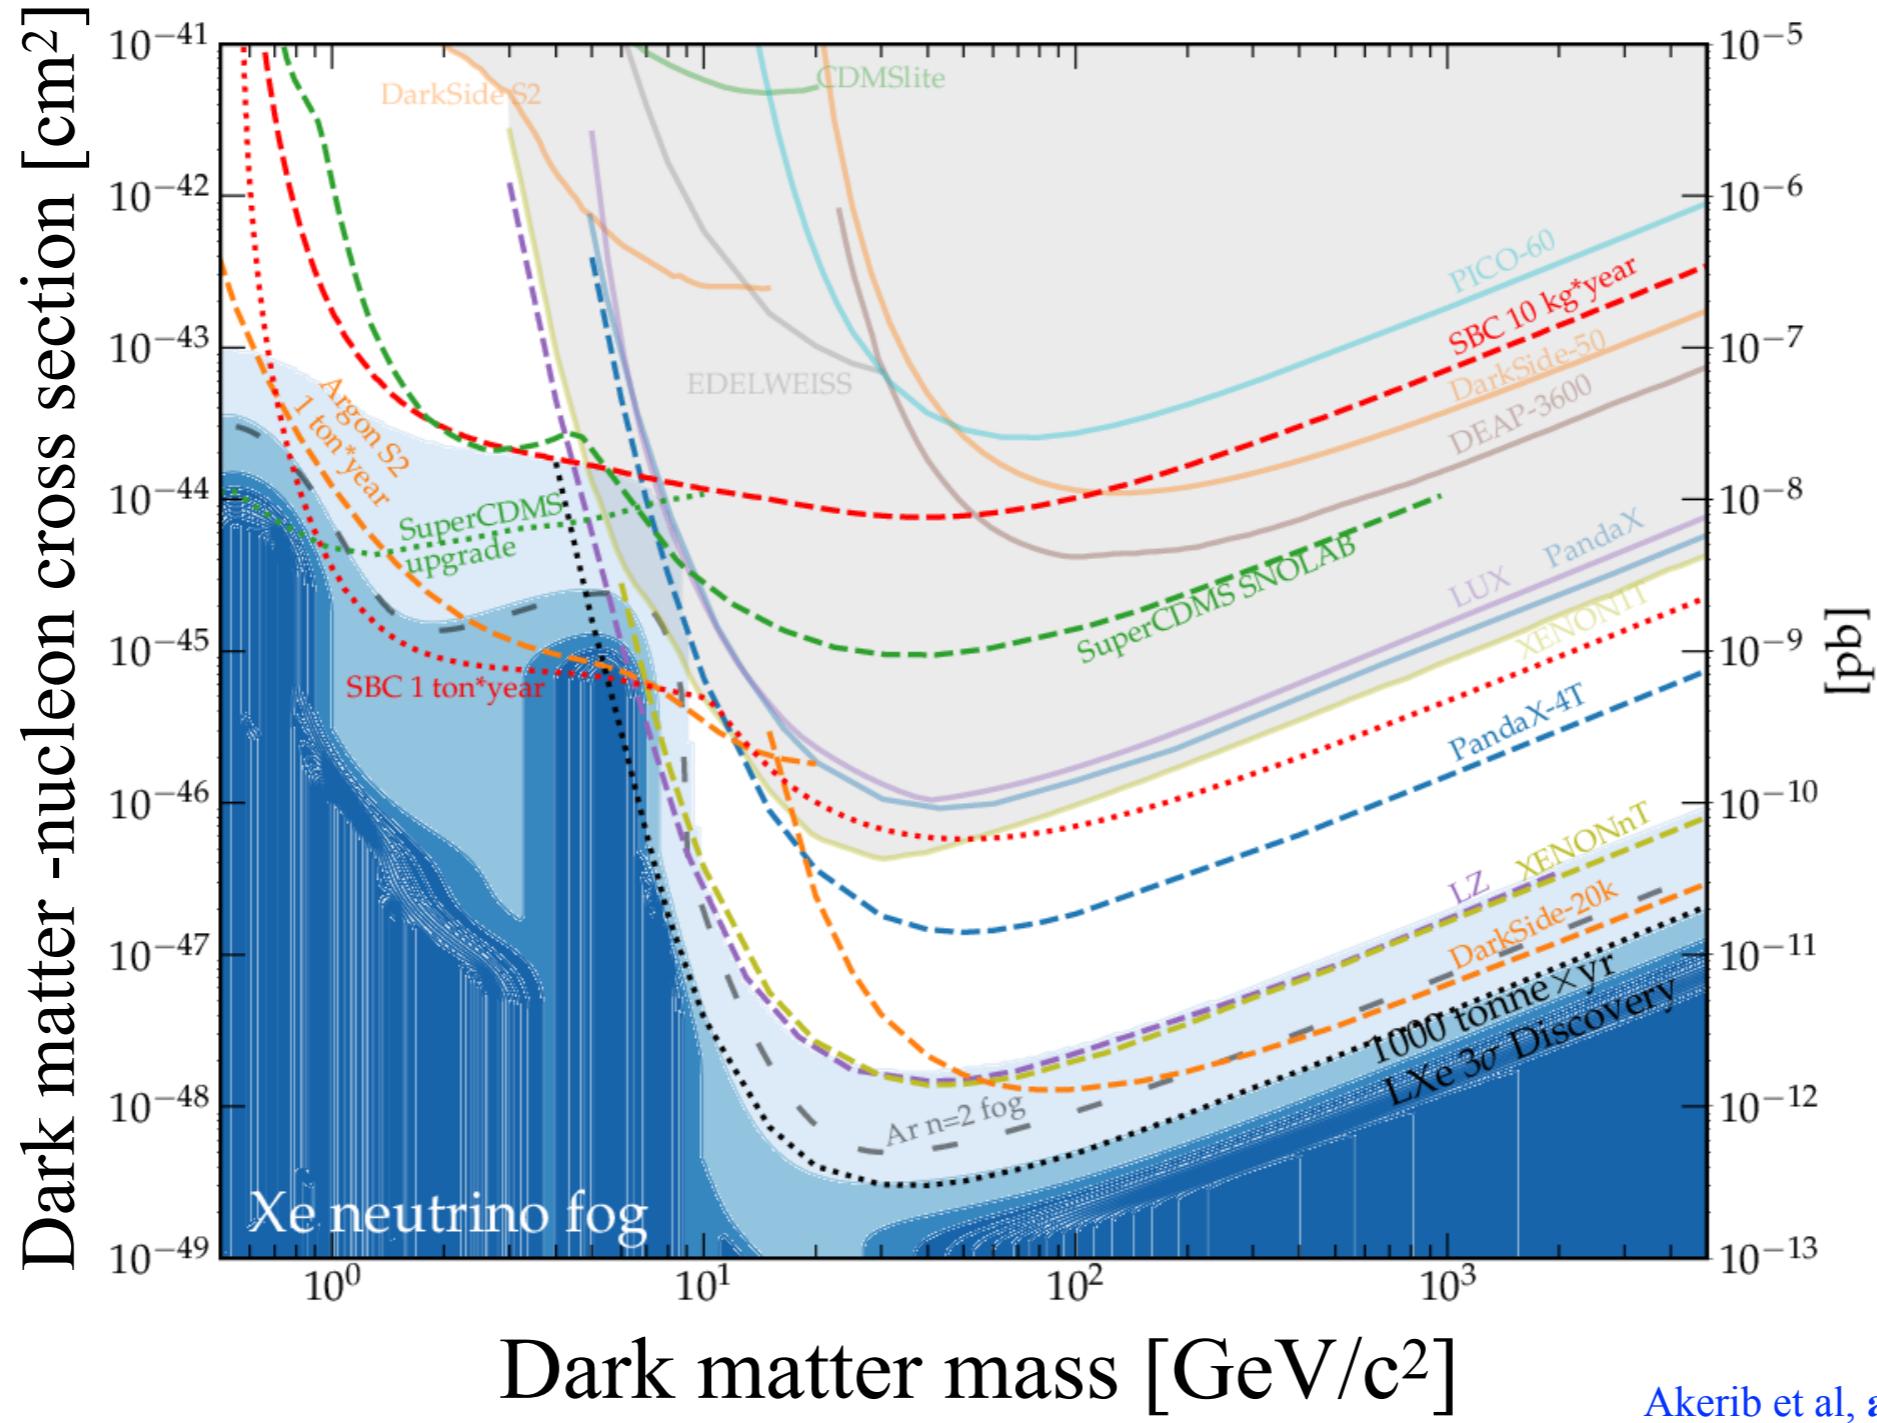

Leane et al, Phys.Rev.D 98 (2018) 2

ATLAS Collaboration JHEP05(2019)142

Current status of DM direct detection

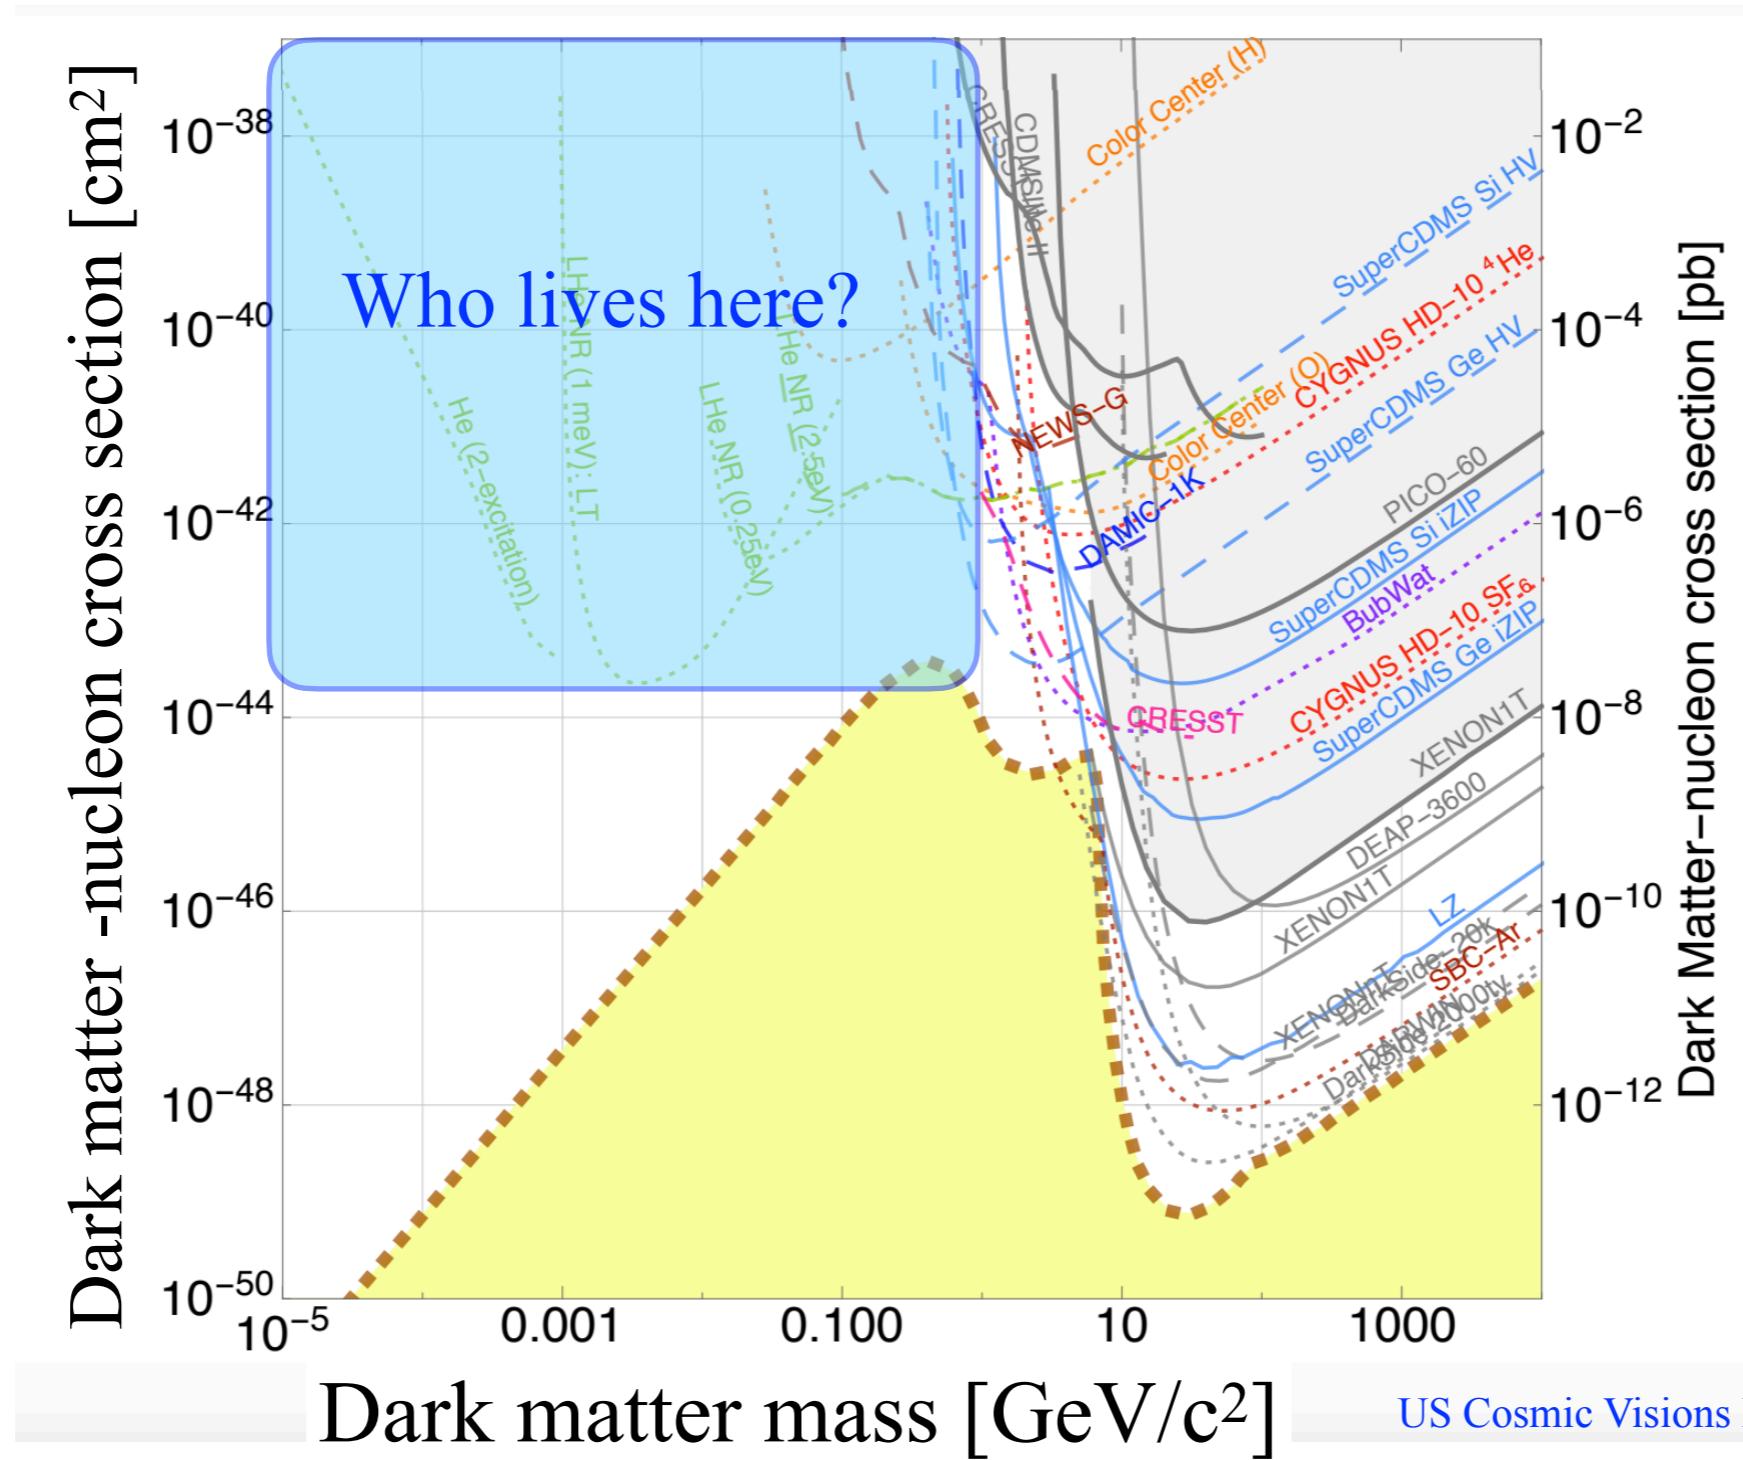

Akerib et al, arXiv: 2203.08084

Very little parameter space left in *traditional* WIMP mass range (1 GeV - 100 TeV)

Larger detectors gives us more sensitivity, but “**Neutrino Floor/fog**” may be challenging

WIMPs remain highly motivated

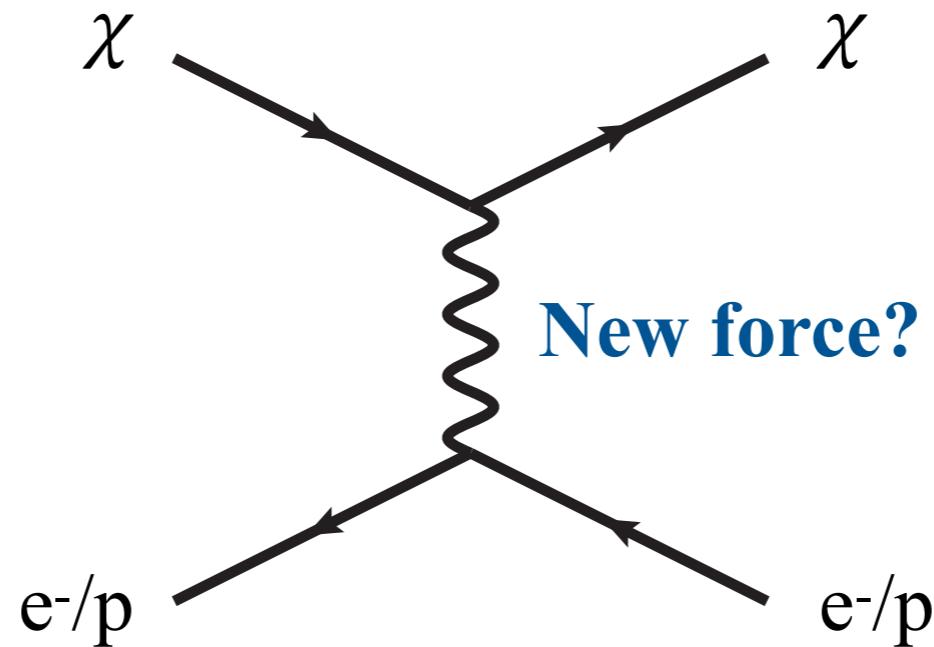

We are compelled to move beyond the WIMP scale

Many opportunities to explore here

Low mass (sub-GeV) DM searches are:

1. Complementary to WIMP searches
2. Very well motivated:

e.g. low mass DM coupled through new hidden sector mediator presents a good target to understand DM production in the early universe

- Thermal freeze-out
- Freeze-in
- Asymmetric

Big stumbling block is that light DM is **invisible** to current WIMP searches

Many nuclear recoil experiments have \sim keV recoil thresholds

Recoil energy caused by galactic DM with $v \sim 10^{-3} c$

$$E_{nr} \sim \frac{\mu_{xN}^2 v^2}{m_N}$$
$$\sim 19 \text{ eV} \left(\frac{m_\chi}{500 \text{ MeV}} \right)^2 \left(\frac{100 \text{ GeV}}{m_N} \right)$$
$$\ll \text{keV}$$

To probe lower masses need very low threshold nuclear recoil detectors

or

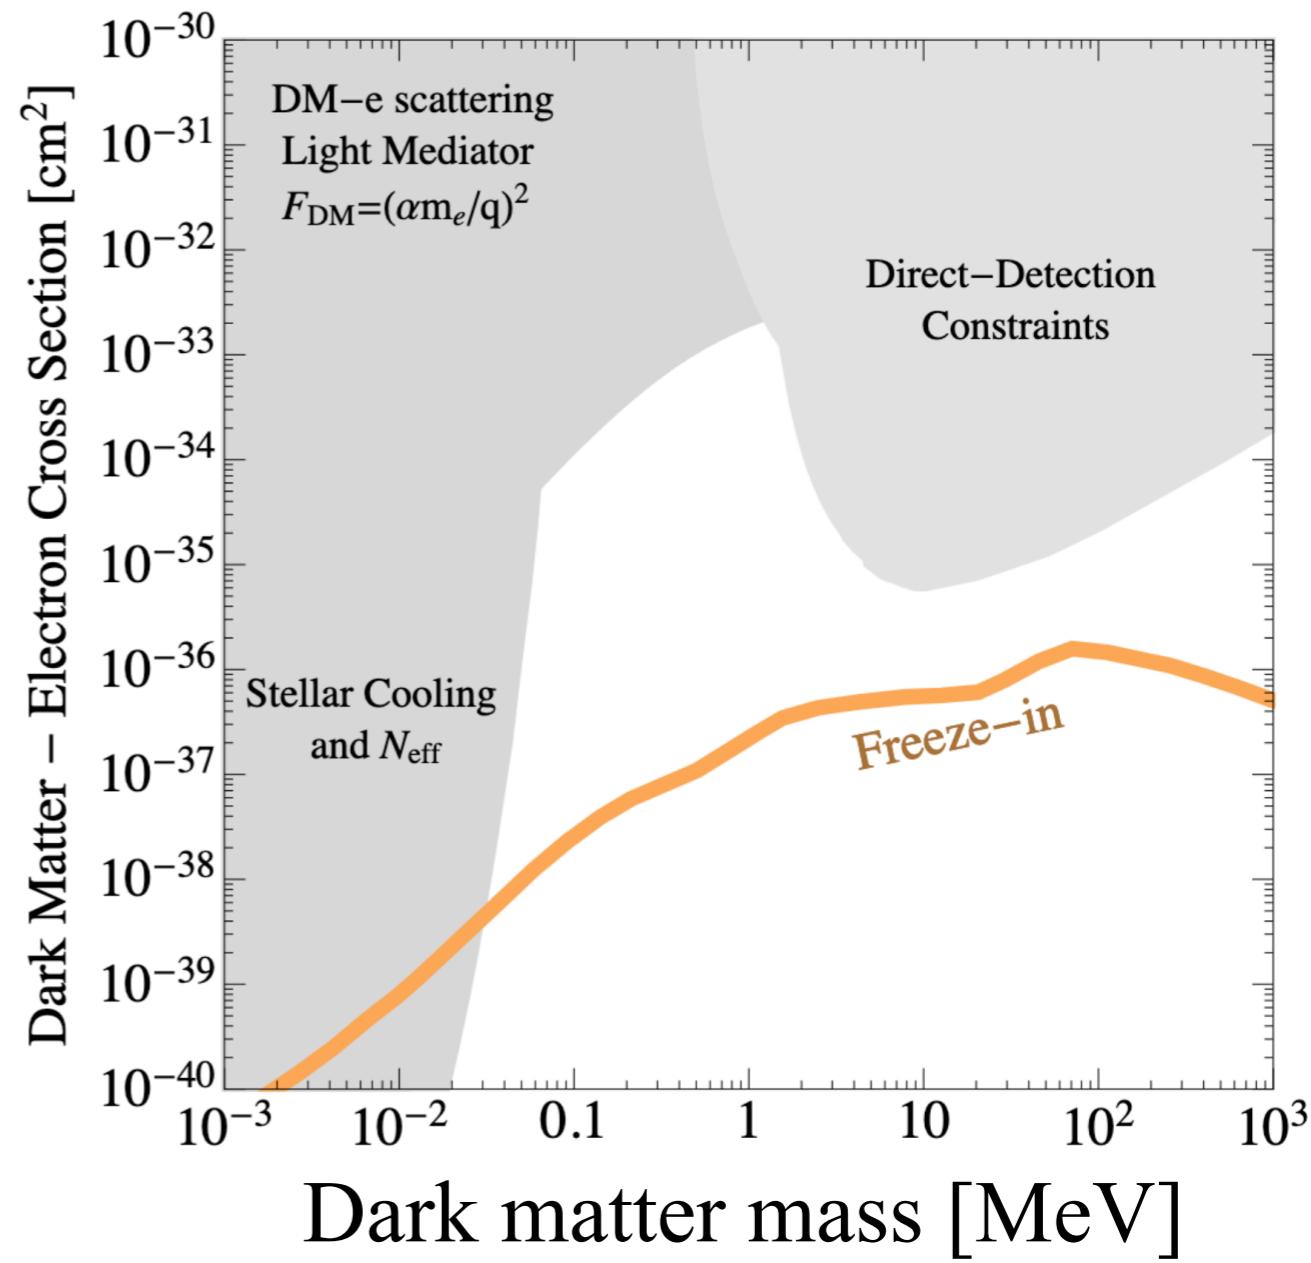

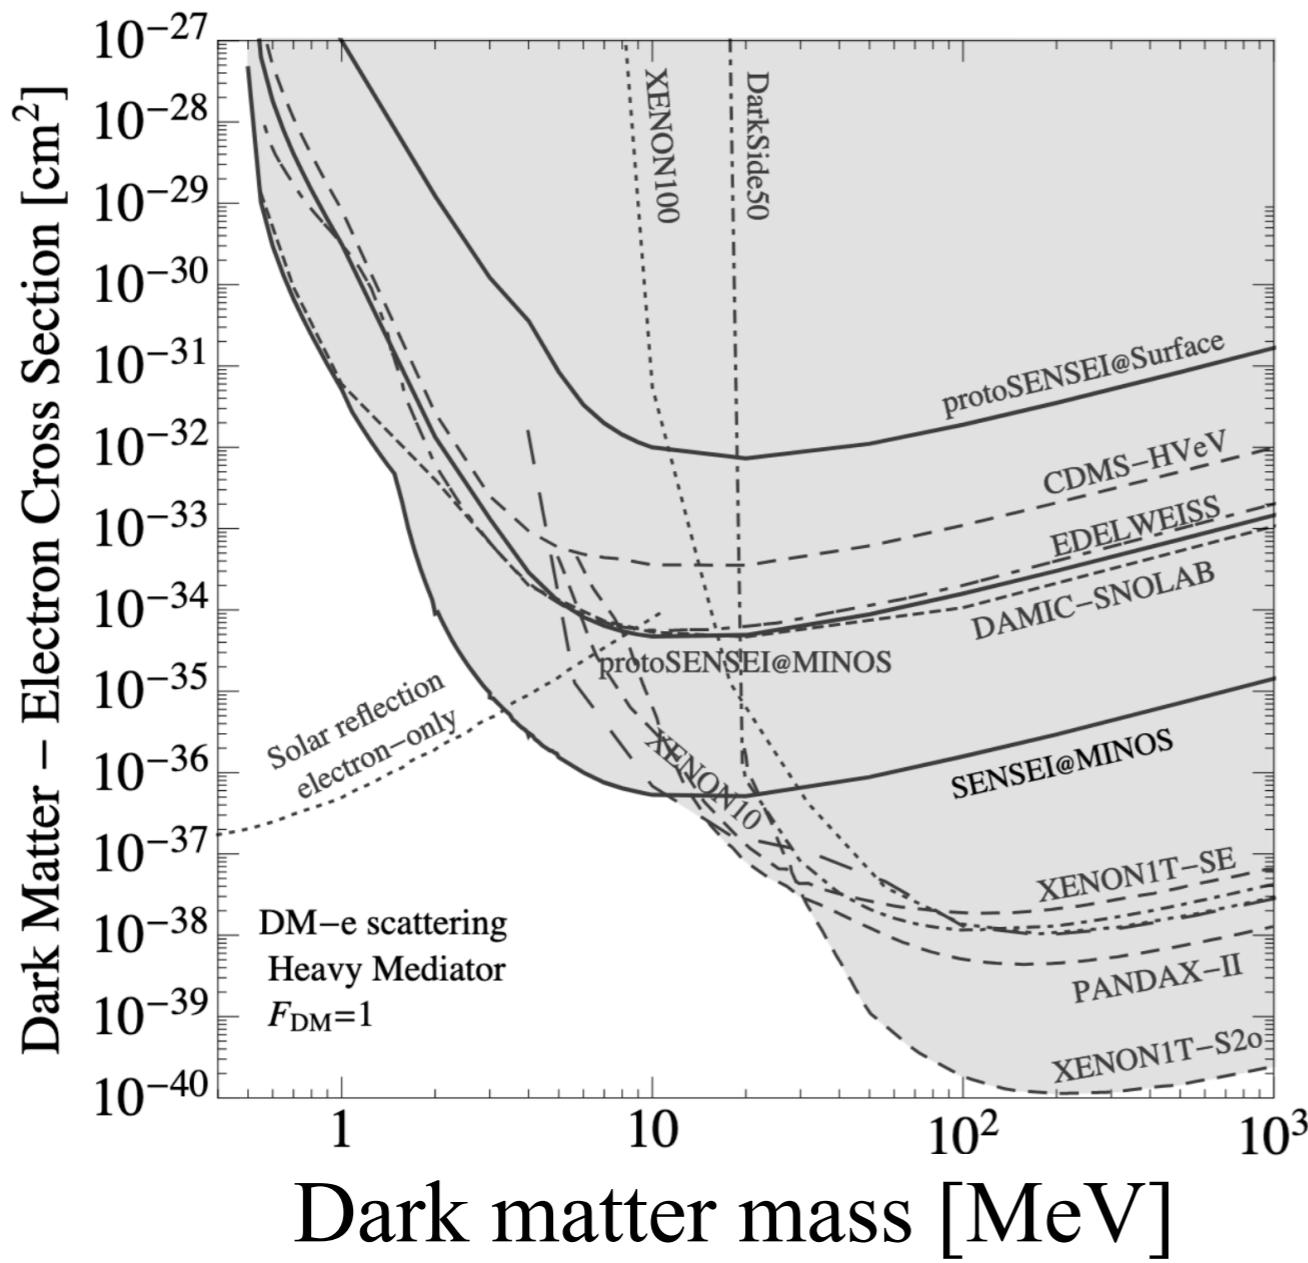

Other ways to maximize energy transfer to the target

Look for DM hitting lighter target to maximize energy transfer

Dark matter - electron scattering

Current searches include:

- Large volume noble liquid detectors
- Small scale semi - conductor detectors

Complementary way to maximize energy transfer to target is

Fast moving/accelerated dark matter

- Energy transferred to nucleus

$$E_{nr} \sim 50 \text{ keV} \left(\frac{m_\chi}{500 \text{ MeV}} \right)^2 \left(\frac{100 \text{ GeV}}{m_N} \right) \left(\frac{v}{0.1} \right)^2$$

- Max energy transferred to electron

$$E_{er} \lesssim 2 \text{ MeV} \left(\frac{m_\chi}{500 \text{ MeV}} \right) \left(\frac{v}{0.1} \right)^2$$

These are above \sim keV threshold energies in **current dark matter detectors** & actually **some large neutrino detectors**

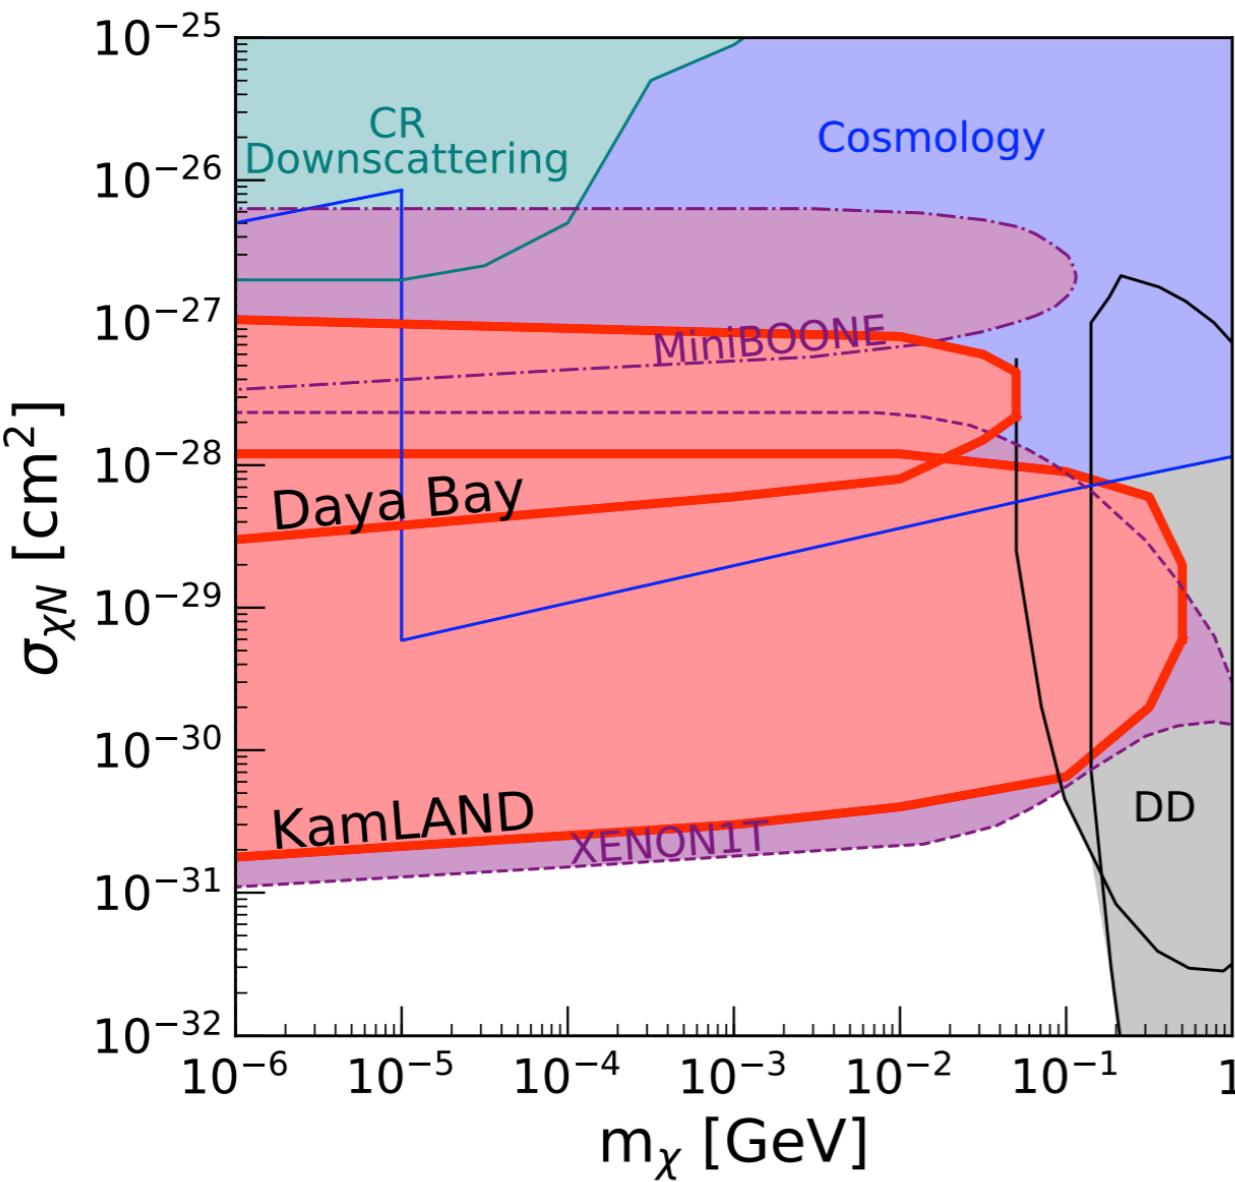

But, galactic DM has to be **non-relativistic**

Accelerated DM must be small subcomponent total halo DM

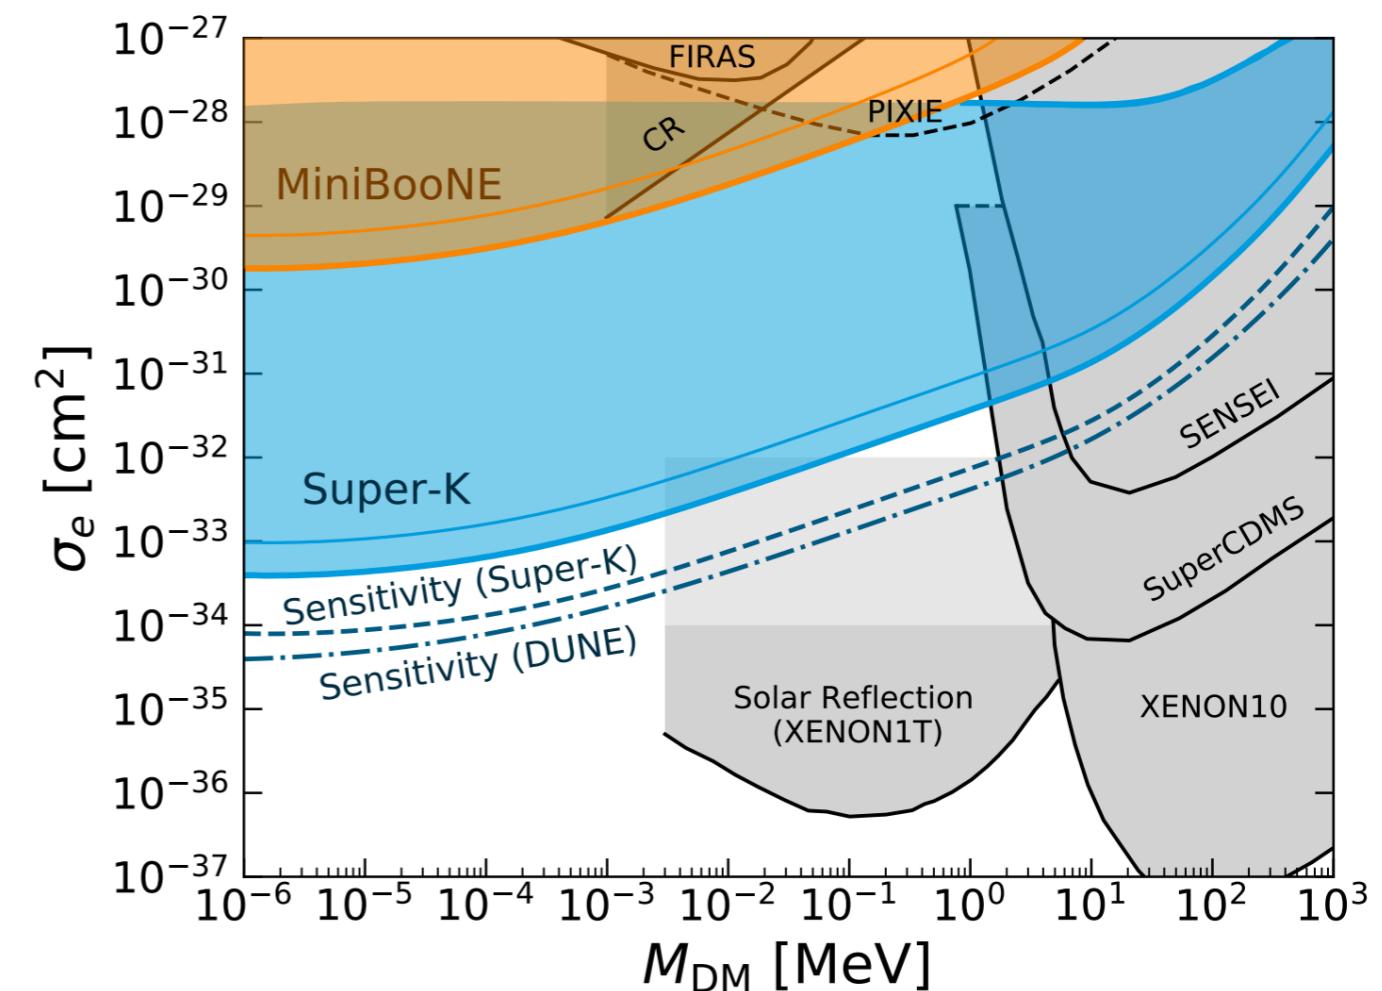

Many ways to get accelerated dark matter

Cosmic ray accelerated dark matter

- High energy CR can scatter off DM moving at $v \sim 10^{-3}$ c
- CR transfers energy to DM, accelerating it
- Accelerated DM reaches earth and scatters in detectors

Chao et al, arXiv: [2108.05608](https://arxiv.org/abs/2108.05608)

Acceleration from supernova shockwaves

Cappiello et al, Phys. Rev. D (107) 2023 3, 035003

A different mechanism (doesn't depend on accelerating SM particle flux)

Dark sector may be non-minimal, i.e. more than one stable DM state

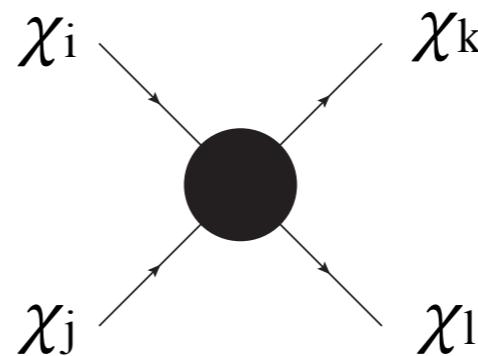

Generic feature of any non-minimal dark sector: small fraction of DM today may be relativistic/semi-relativistic

Sources:

- Assisted Freeze-out:

$$\chi_i \chi_j \rightarrow \chi_k \chi_l$$

with $\chi_i \chi_j > \chi_k \chi_l$

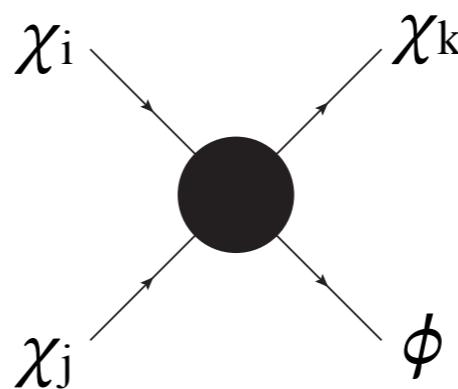

Belanger and Park : JCAP 03 (2012) 038

- Semi-annihilation:

$$\chi_i \chi_j \rightarrow \chi_k \phi$$

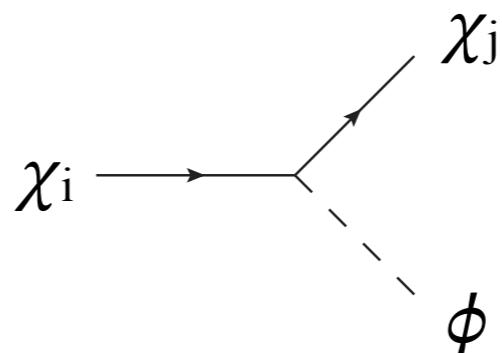

, Z₃ DM symmetry

D'Eramo and Thaler : JHEP 06 (2010) 109

- Decay:

$$\chi_i \rightarrow \chi_j \phi$$

Tucker-Smith & Weiner: Phys.Rev. D64 (2001) 043502

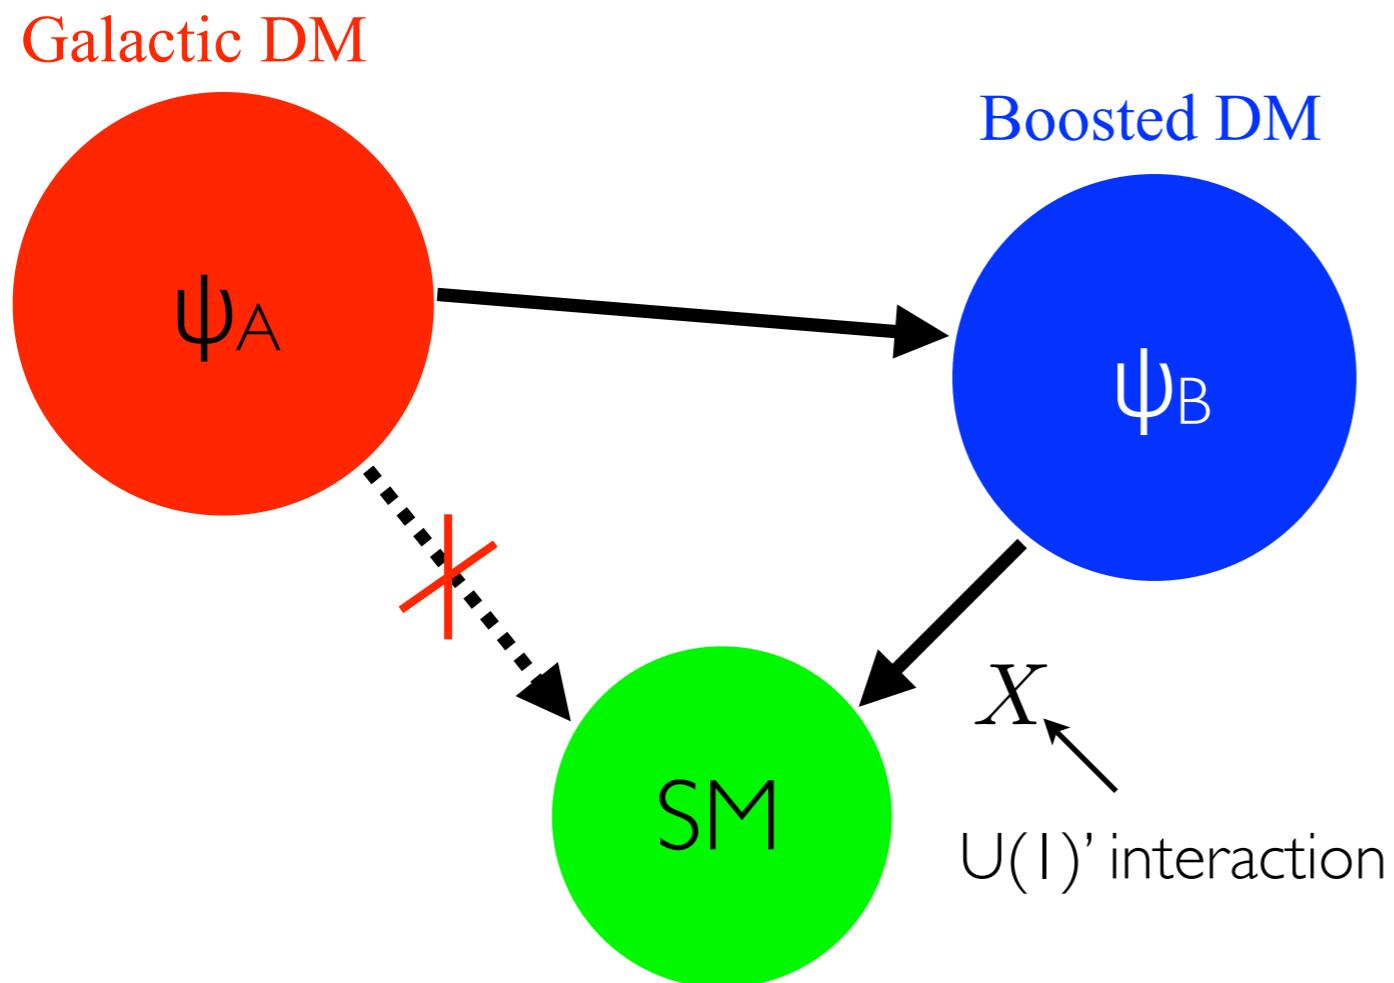

Mohlabeng : Phys.Rev. D99 (2019) 11, 115001

+ many others

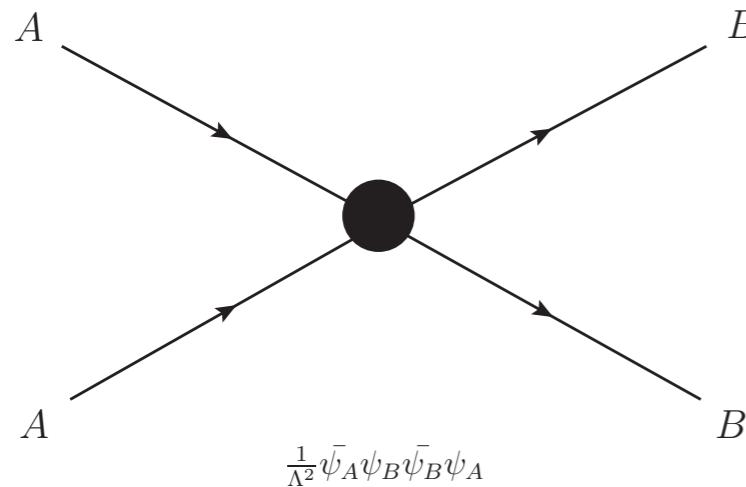

Boosted dark matter

- Two stable DM particle, ψ_A & ψ_B with $m_A > m_B$ (eg. $U(1)' \otimes U(1)''$)

For example:

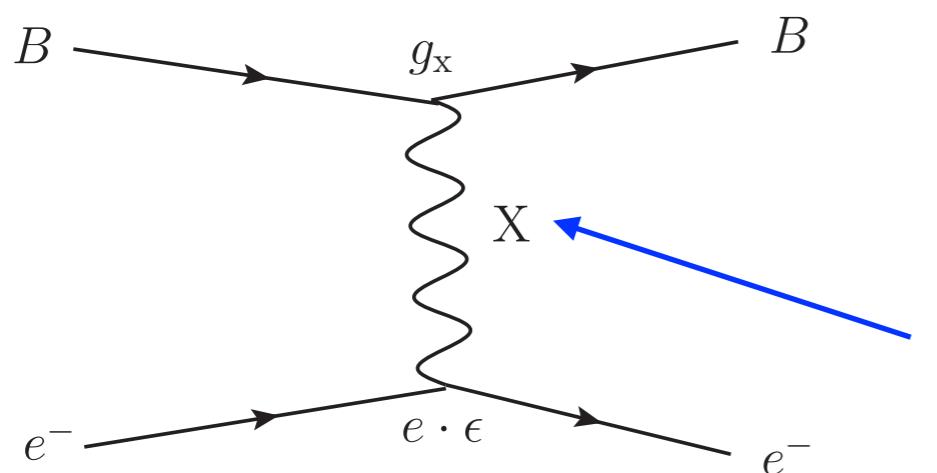

- ψ_A is the dominant DM component and has no direct coupling to SM
- ψ_B is sub-dominant and couples to SM through new force

- ‘A’ particles self-annihilate producing accelerated ‘B’ particles with boost factor

$$\gamma = m_A/m_B$$

$$\frac{1}{\Lambda^2} \bar{\chi}_A \chi_B \bar{\chi}_B \chi_A$$

- boosted DM particles travel to Earth and scatter with SM in the detector

- Interacts through some light mediator particle **X**

Agashe, et al : **JCAP 10 (2014) 062**

Boosted dark matter from the Galactic Center

Annihilation of A to boosted B in the Galactic Center

Flux: NFW profile + 10° cone around GC

$$\Phi_{GC}^{10^\circ} = 9.9 \times 10^{-8} \text{ cm}^{-2} \text{ s}^{-1} \left(\frac{\langle \sigma_{A\bar{A} \rightarrow B\bar{B}} v \rangle}{5 \times 10^{-26} \text{ cm}^3/\text{s}} \right) \left(\frac{20 \text{ GeV}}{m_A} \right)^2$$

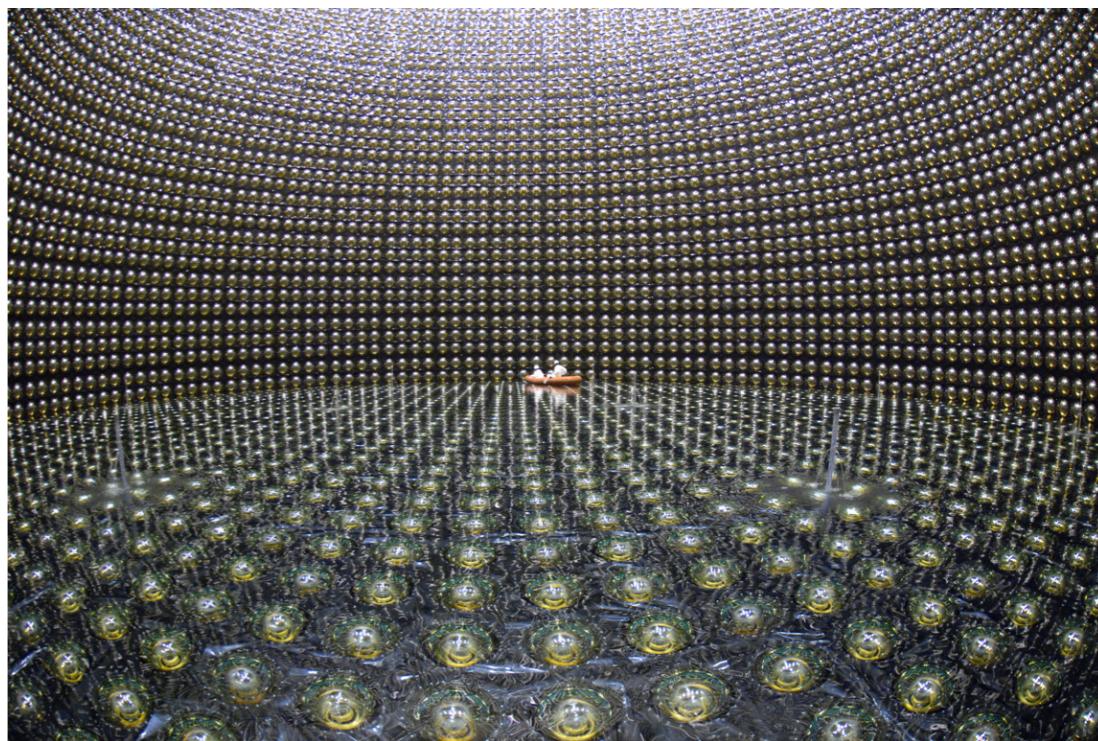

Lower flux means we need large volume detectors for sensitivity

Neutrino detectors: Super-K, Hyper-K, Ice-Cube, DUNE

Dark matter detectors: XENON1T, DarkSide

Focus on electron scattering

For nucleon scattering:

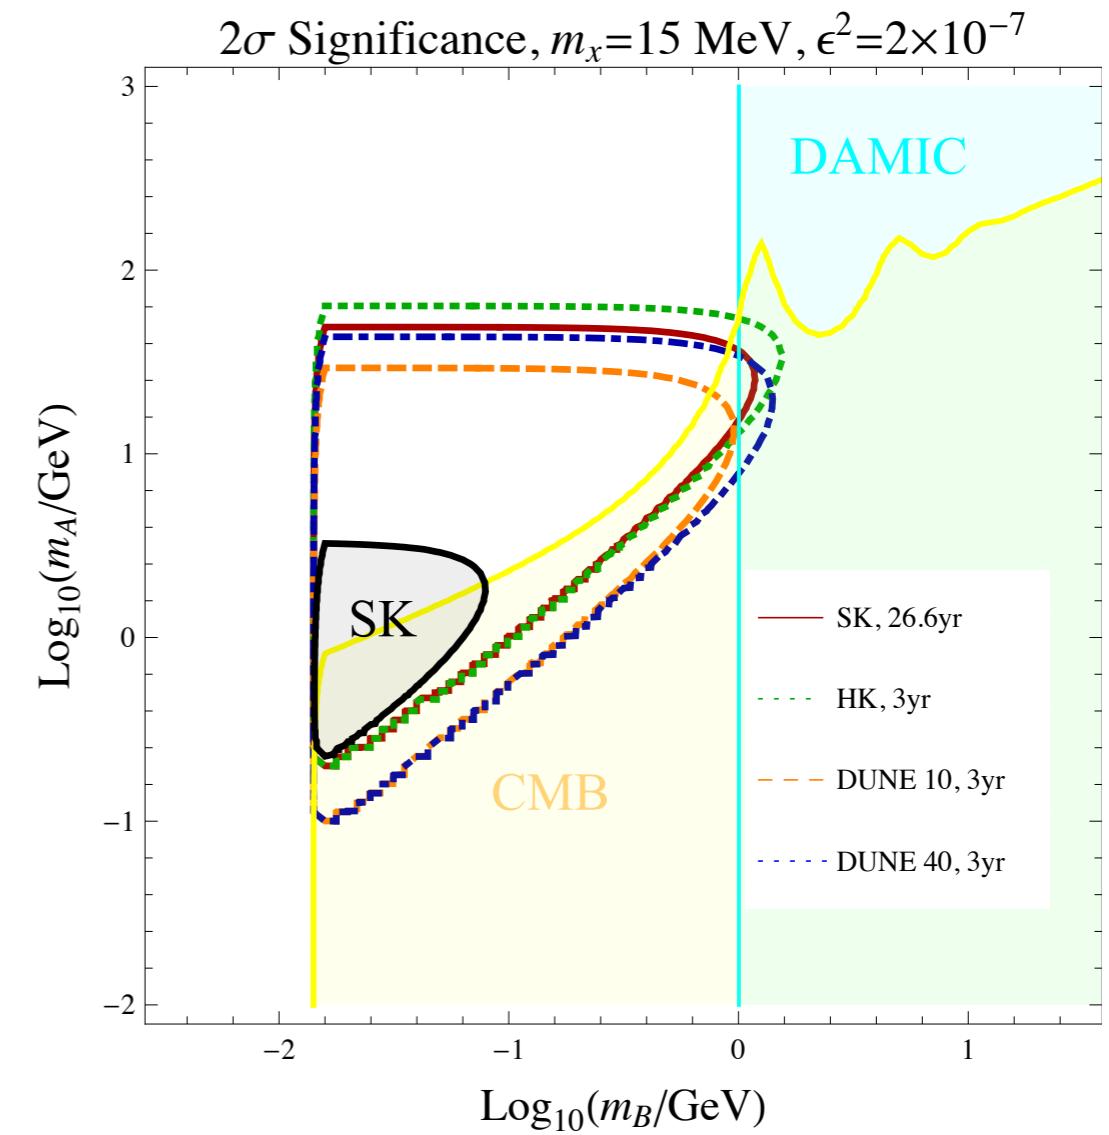

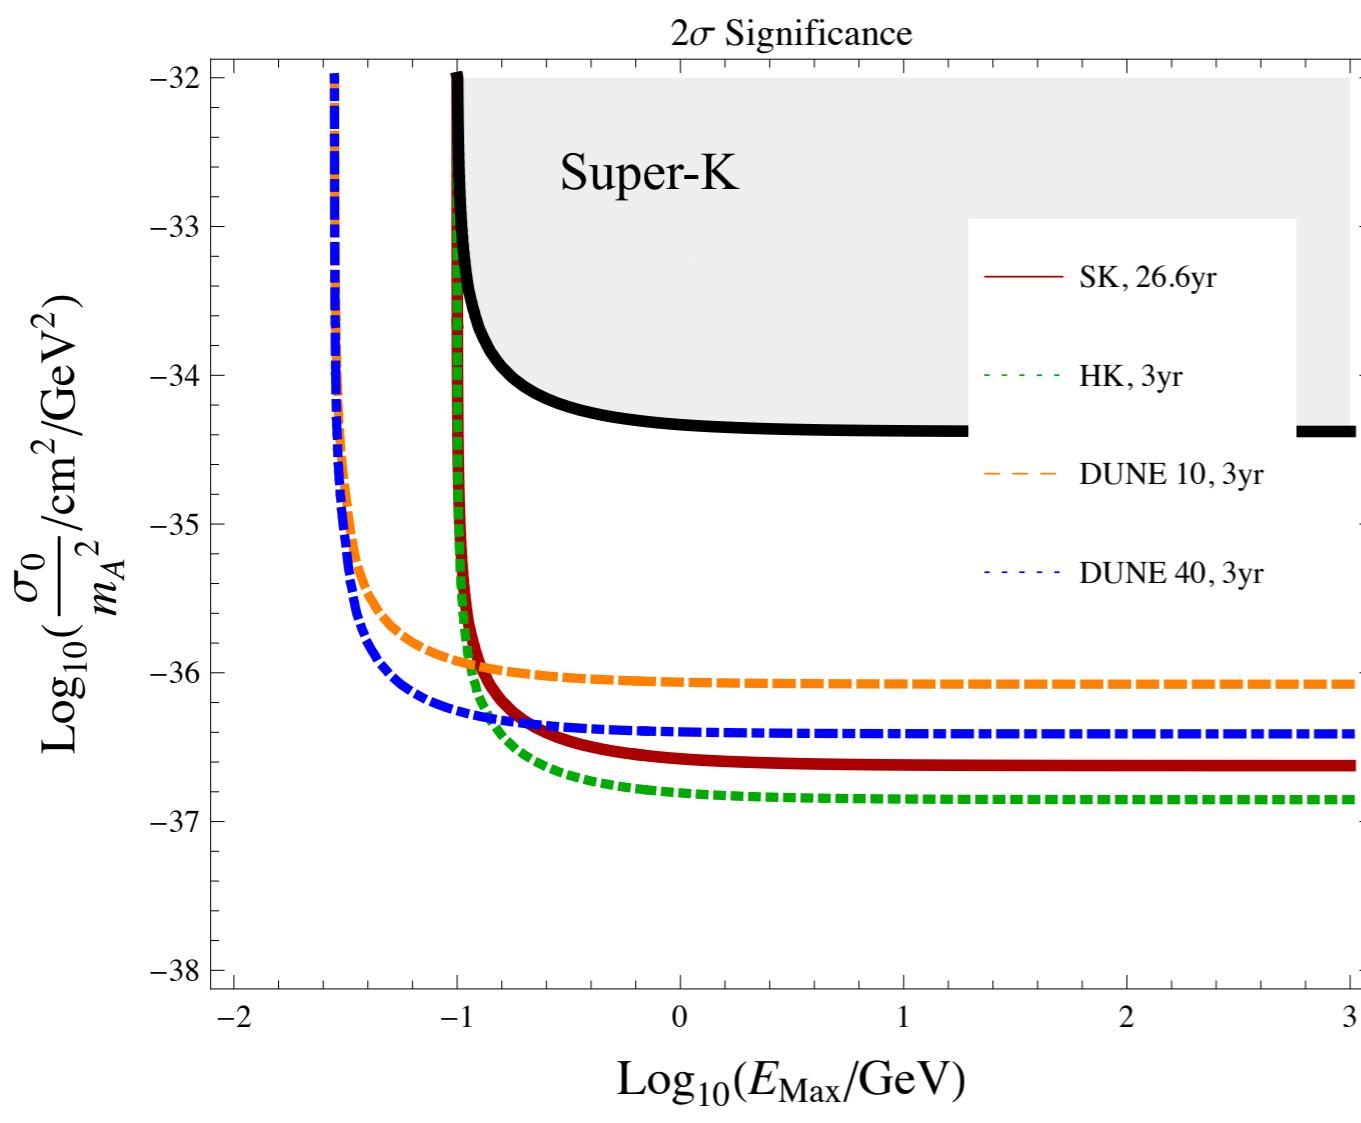

Boosted DM from the Galactic Center

2σ sensitivity:

$$N_{\text{sig}} = \Delta T N_{\text{target}} \Phi_{\text{GC}}^{10^\circ} \int_{E_{\text{thres}}}^{E_{\text{max}}} dE_e \frac{d\sigma_{\text{Be}^- \rightarrow \text{Be}^-}}{dE_e}$$

$$S^{\theta_{\text{res}}} = \frac{N_{\text{sig}}}{\sqrt{N_{\text{BG}}^{\theta_{\text{res}}}}}$$

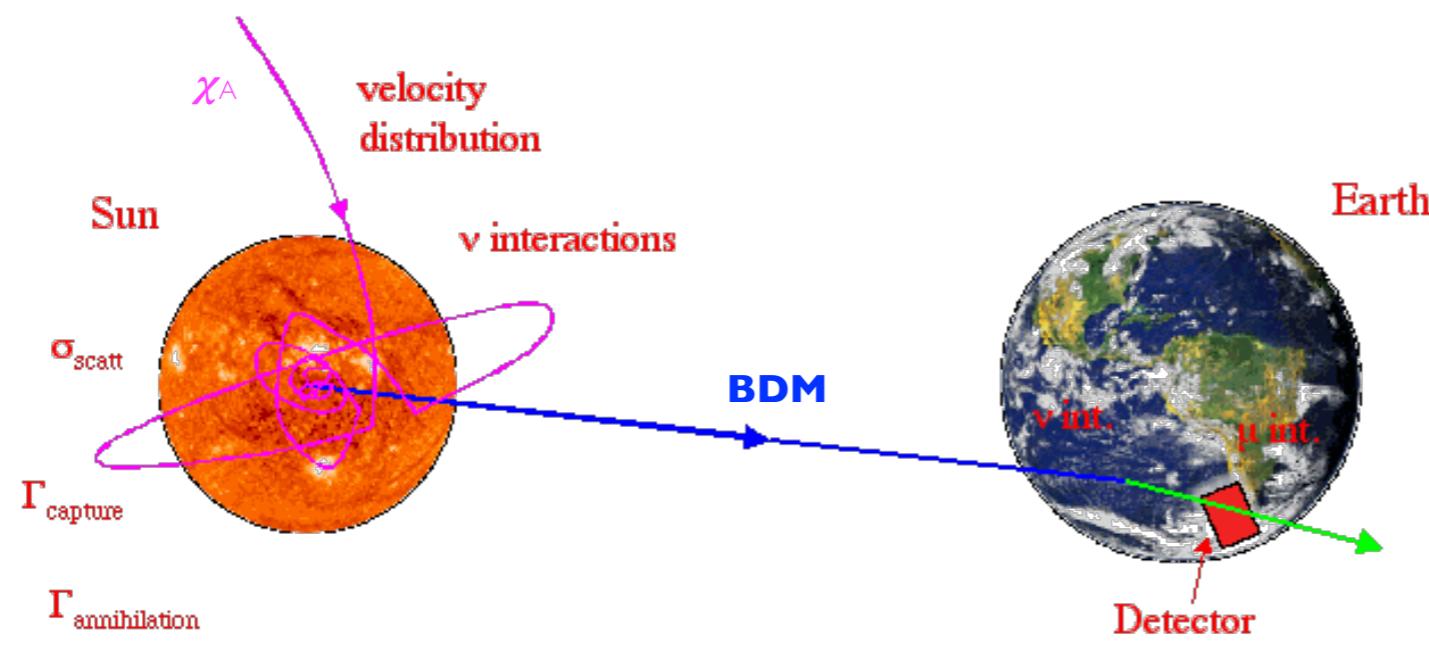

Boosted DM from the Sun

χ_A can get captured in the Sun and annihilate to χ_B

χ_B travel to earth and scatter in the detector

The Sun is a point-like source so we don't consider an observation angle

Including self-interactions enhances the capture rate in the Sun

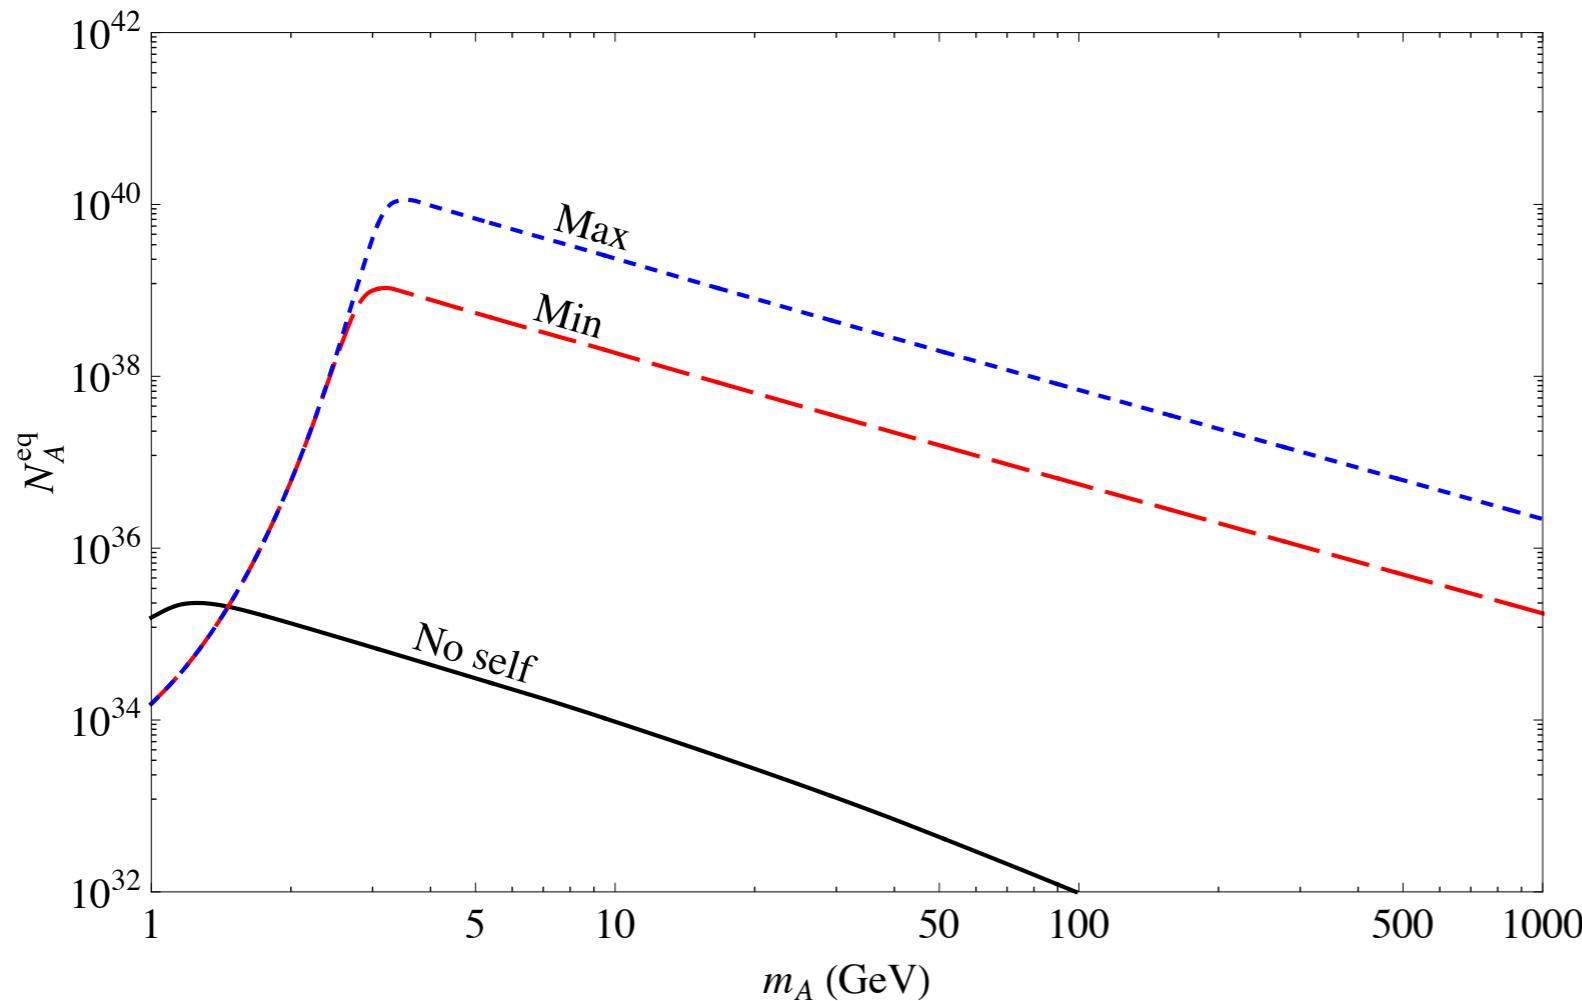

Kong, Mohlabeng, Park: [Phys. Lett. B 743 \(2015\) 256-266](#)

Boosted DM at direct detection experiments

- Large volume DD experiments can look for lower A masses

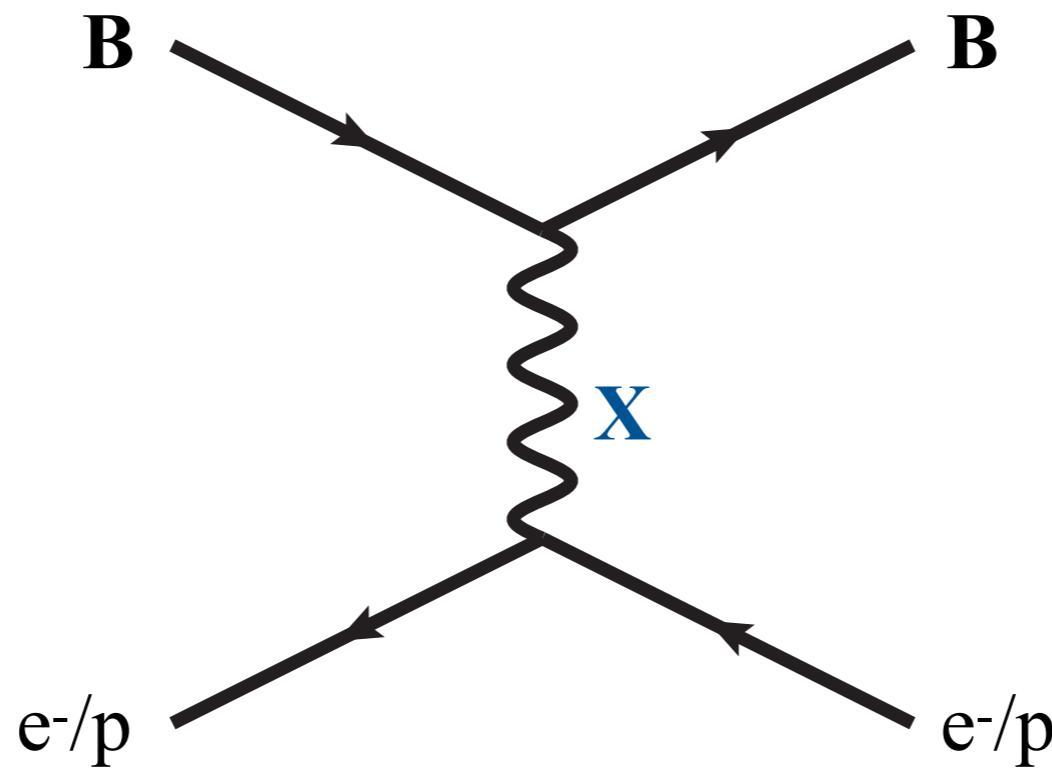

XENON1T

DarkSide

...

} Lower threshold than neutrino detectors

Scattering with either nucleon or electrons

Focus on electron scattering

To obtain recoil rates:

$$N_{sig} = \Phi_B \sigma_{Be} N_e^{eff} t_{exp}$$

BDM flux Scattering cross-section Effective # of electrons exposure time

However, it is important to include atomic effects related to DM - e scattering

$$\frac{dN_{sig}}{dE_{eR}} = \Phi_B t_{exp} N_{Xe} \frac{d\sigma_{Be} v_{rel}}{dE_{eR}}$$

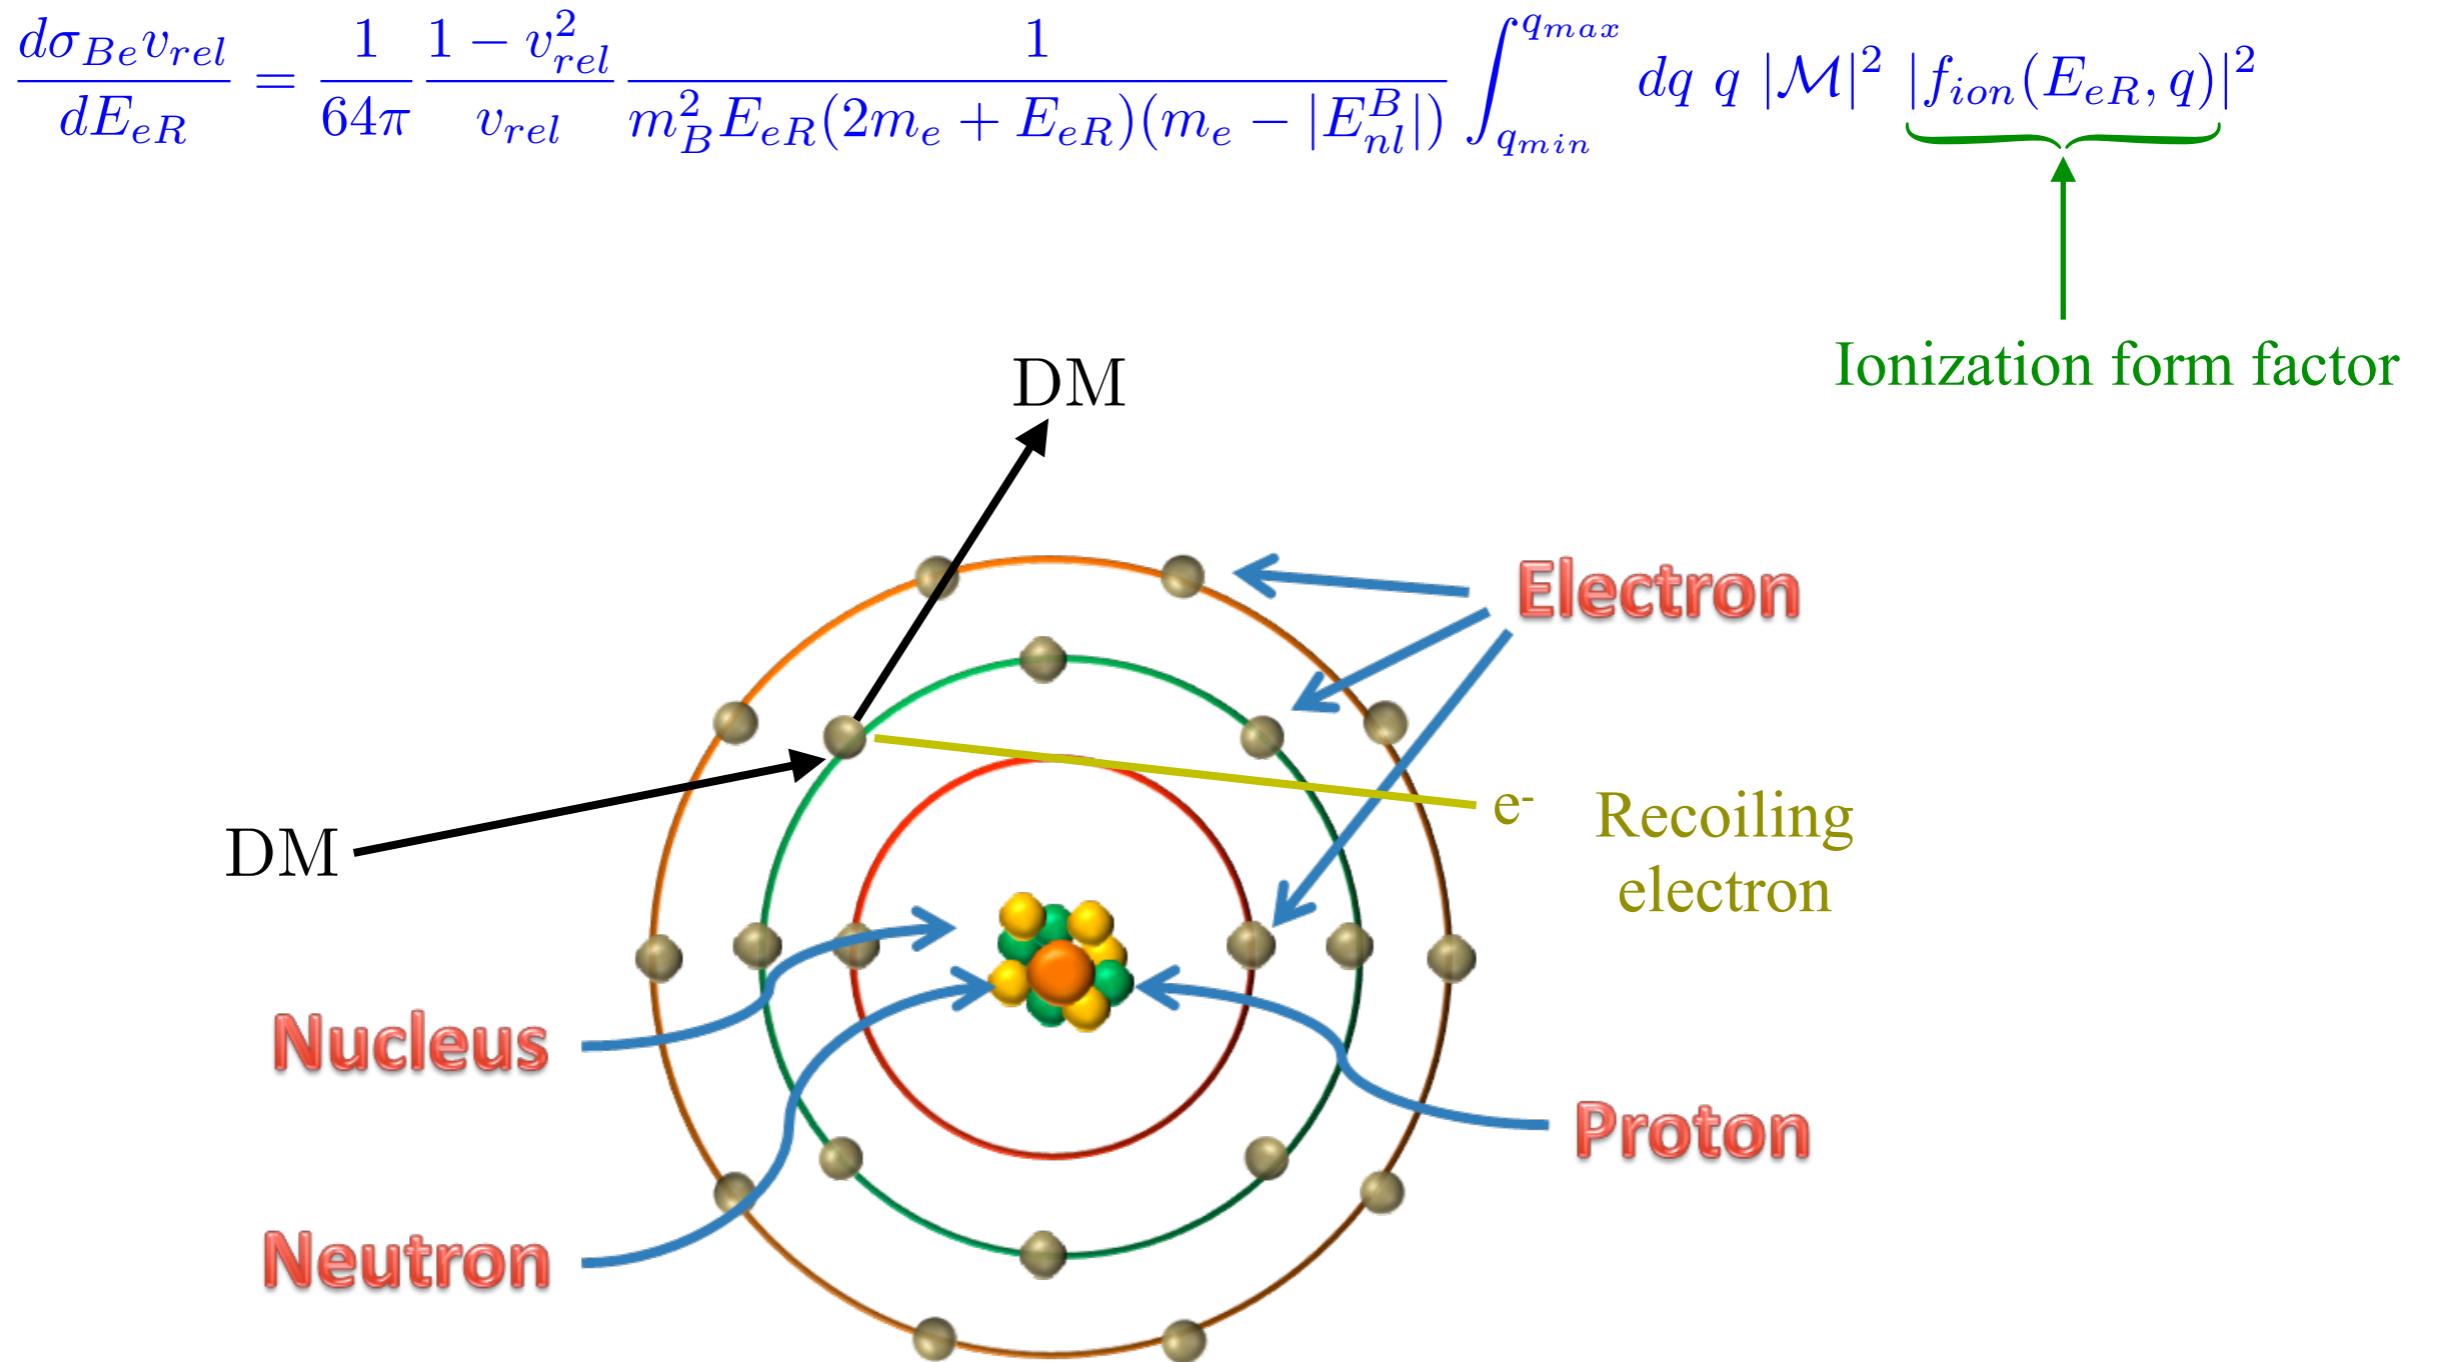

of Xenon atoms in volume

Ionization form factor

Differential scattering cross-section

$$\frac{d\sigma_{Be} v_{rel}}{dE_{eR}} = \frac{1}{64\pi} \frac{1 - v_{rel}^2}{v_{rel}} \frac{1}{m_B^2 E_{eR} (2m_e + E_{eR}) (m_e - |E_{nl}^B|)} \int_{q_{min}}^{q_{max}} dq q |\mathcal{M}|^2 \underbrace{|f_{ion}(E_{eR}, q)|^2}_{\downarrow}$$

Ionization effects:

- Bound electrons have non-negligible momentum dependence
- Ionization function takes into account electron momentum dependence
- Electrons are bound in different orbitals with binding energies, ionization function accounts mom transfer required to ionize electron from orbitals

$$|f_{ion}(E_{eR}, q)|^2 = \frac{2k'^3}{(2\pi)^3} \int dr^3 \psi_{ef}^*(\mathbf{r}) e^{i\mathbf{q}\cdot\mathbf{r}} \psi_{ei}(\mathbf{r})$$

free electron
wave-function
bound electron
wave-function

- Different functions considered

Plane - Wave: bound electron wave function is described by **Roothaan-Hartree-Fock** wavefunctions

Bunge et al: *Atom. Data Nucl. Data Tabl.* **53** (1993) 113-162

Outgoing electron wave function is described by **plane wave**

Essig et al: *Phys. Rev. D* **85** (2012) 076007

Kopp et al: *Phys. Rev. D* **80** (2009) 083502

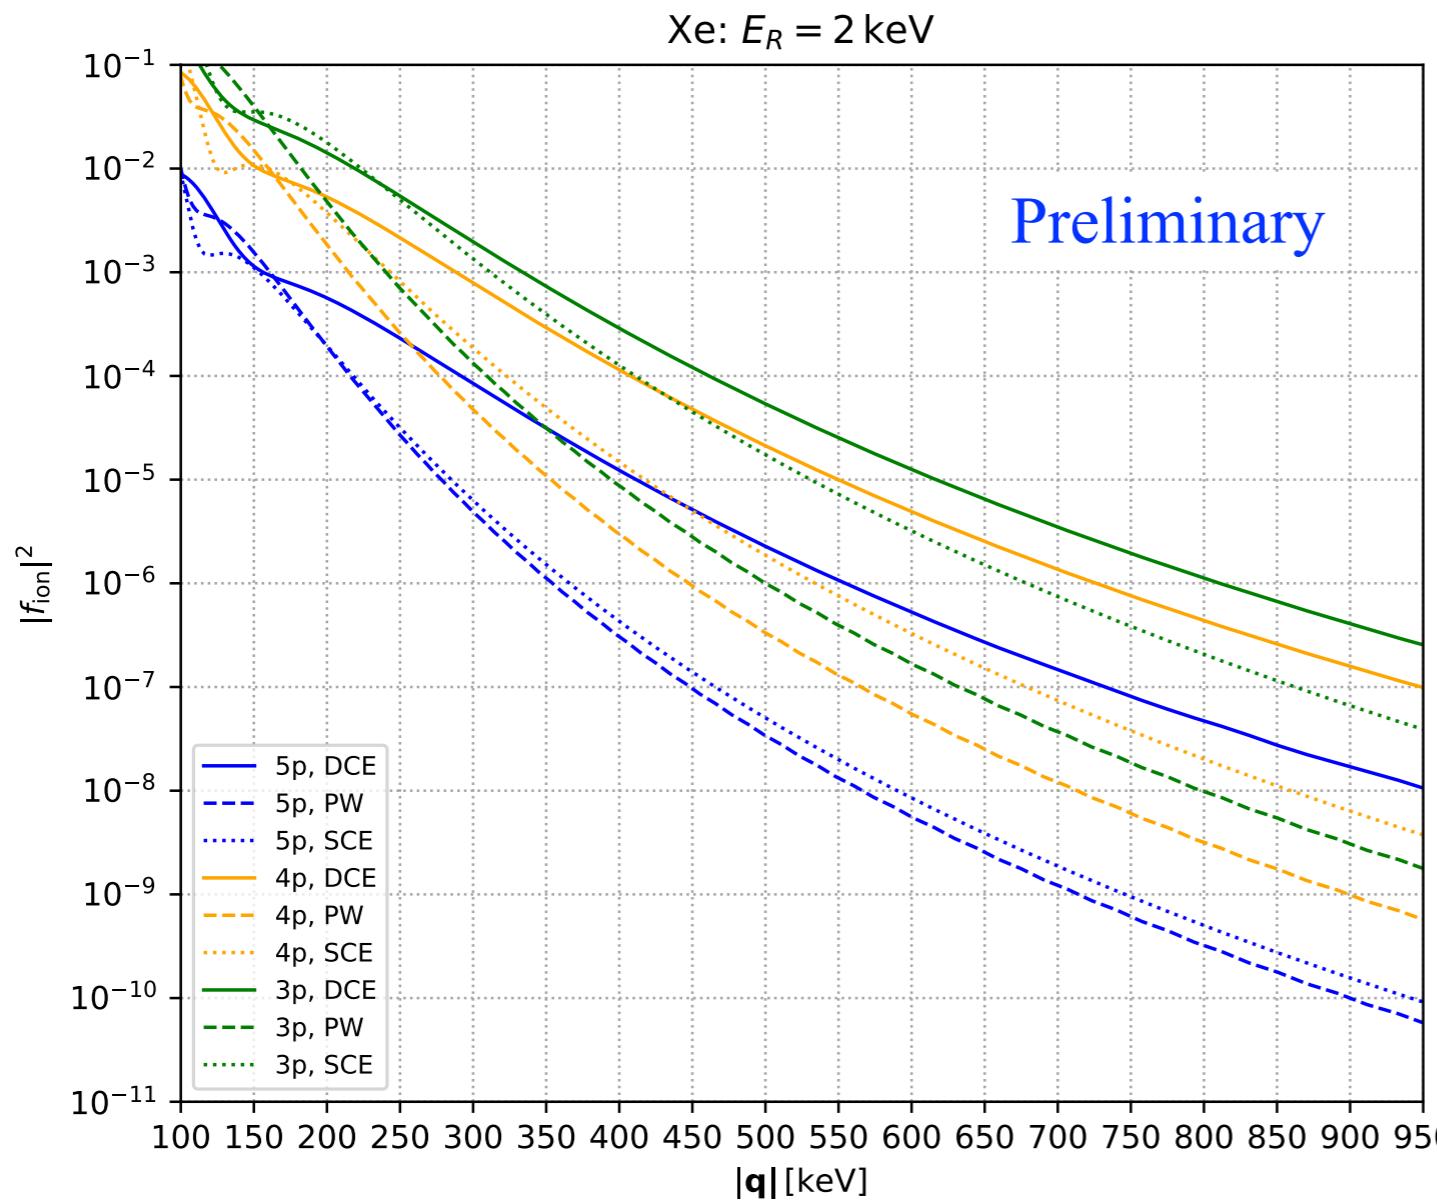

Cao et al: *Chin. Phys. C* **45** (2021) 4, 045002 + many others

Relativistic ionization function: - bound and ionized electron wave functions are obtained by solving relativistic Dirac equation

i.e. solve $\hat{h}\psi_{nk} = E_{nk}\psi_{nk}$

using Dirac hamiltonian $\hat{h} = \alpha \cdot \mathbf{p} + m_e(\beta - 1) + V_{eff}(r)$

- accounts for Lorentz structure of DM - e interactions

Roberts et al: *Phys. Rev. D* **93** (2016) 115037

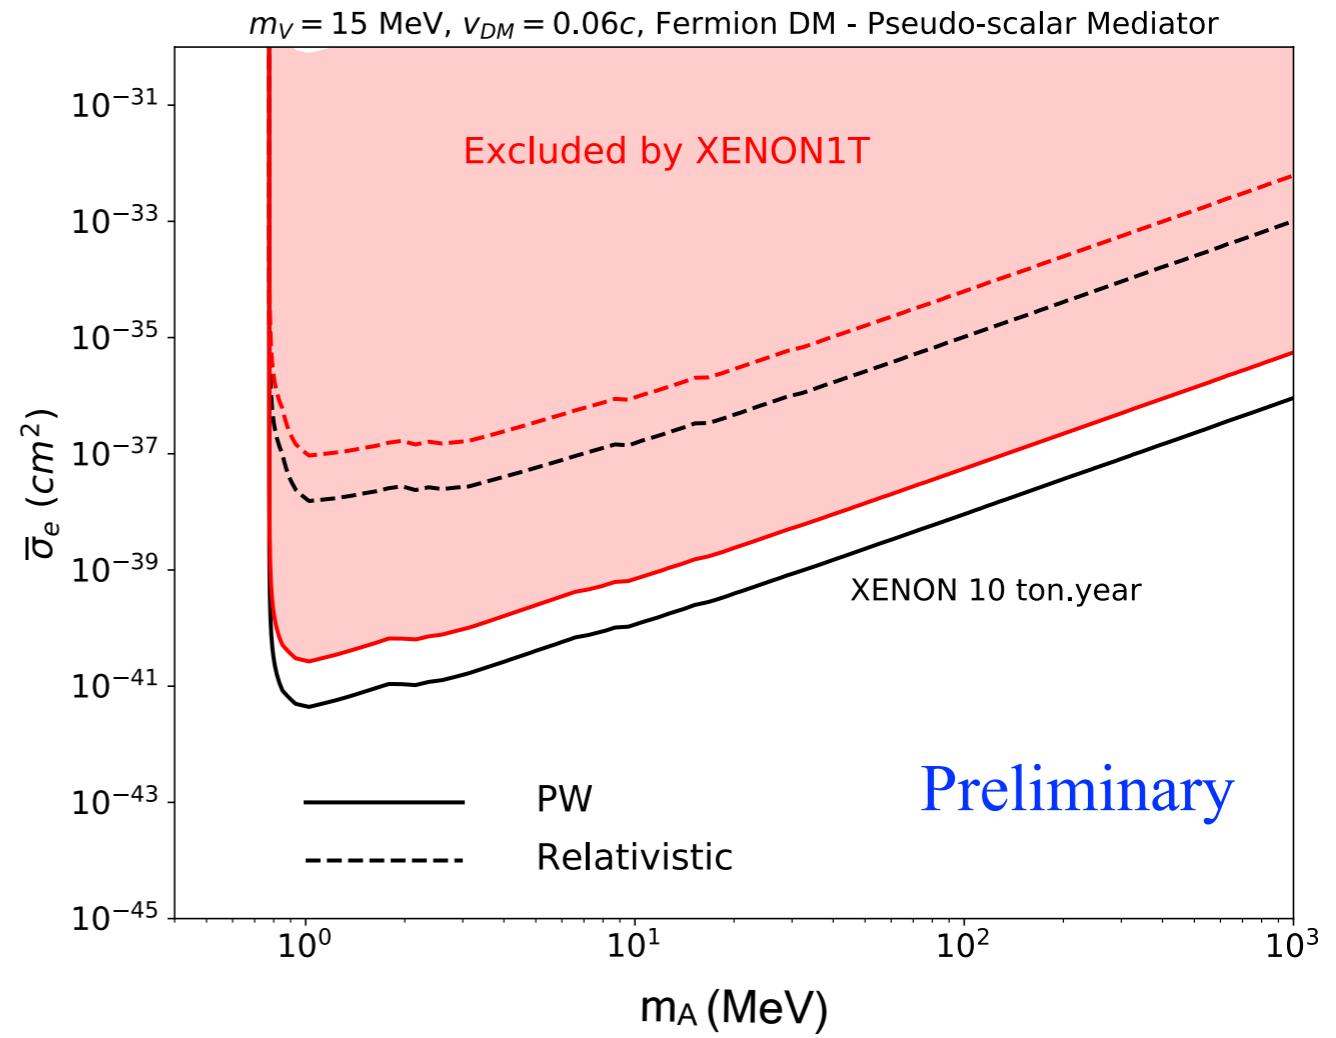

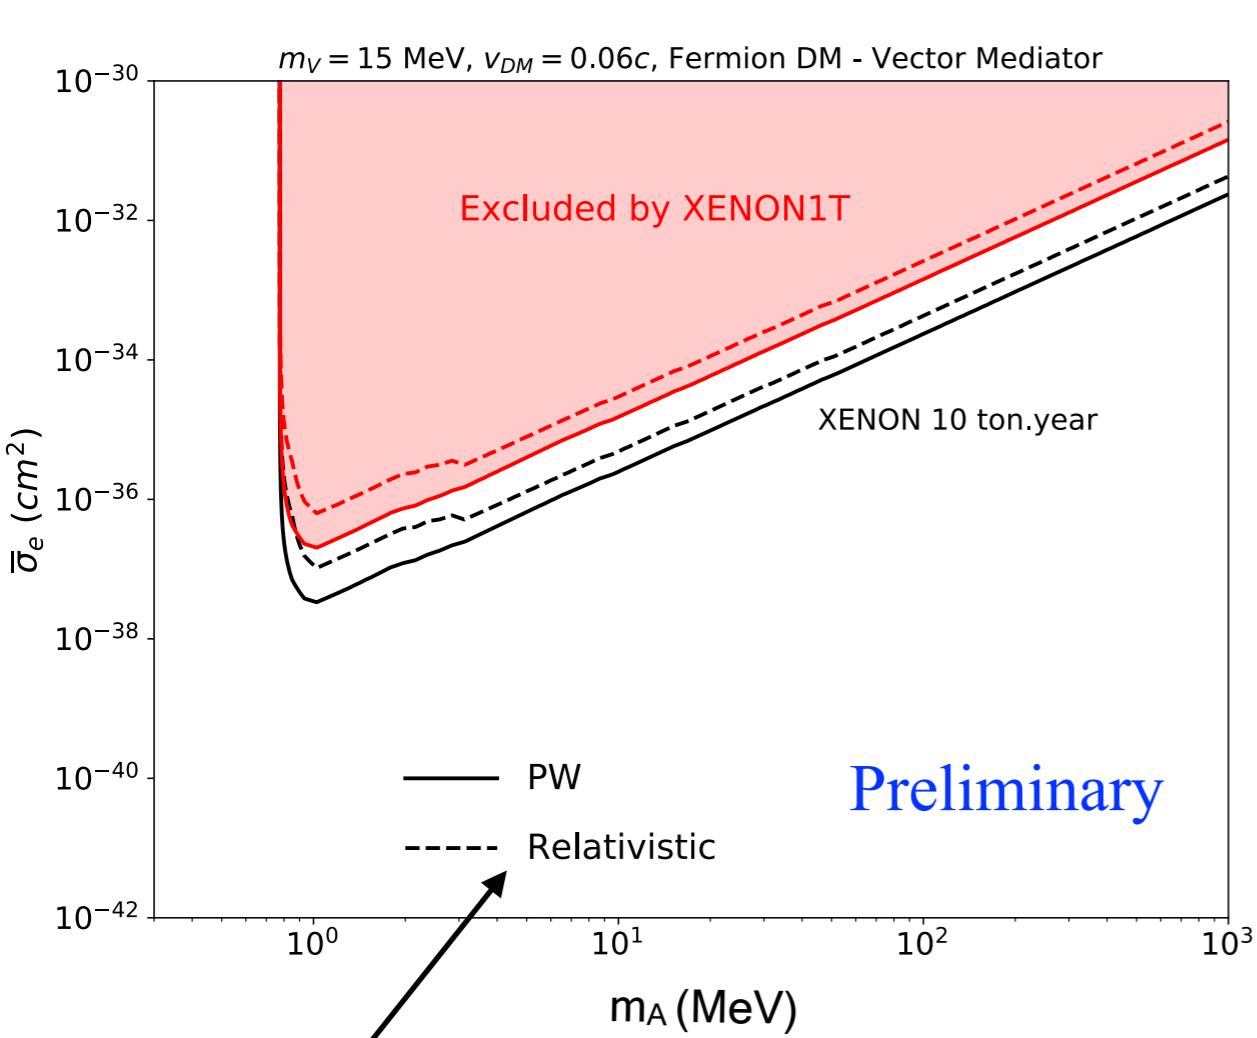

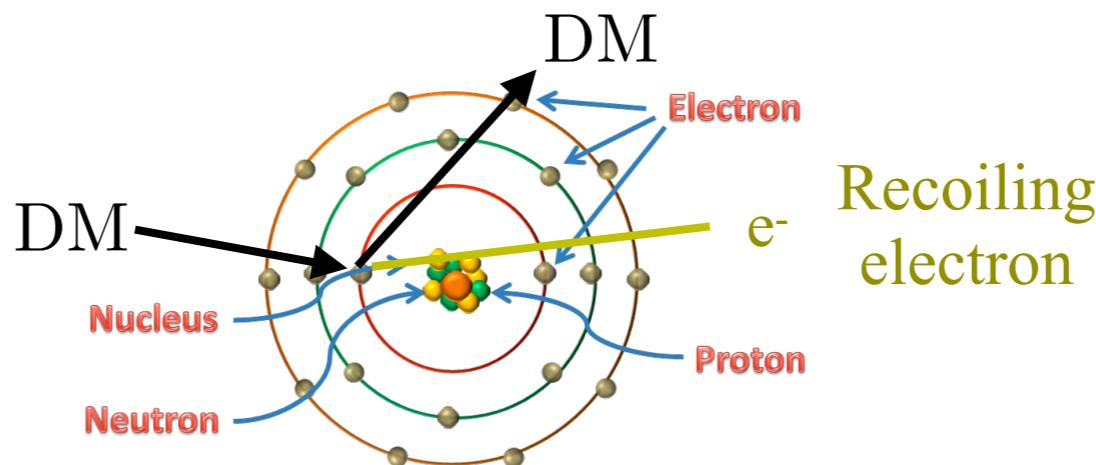

Roberts, Flambaum: *Phys. Rev. D* **100** (2019) 063017

At high momentum transfer,
relativistic & PW are different

Alhazmi, Kim, Kong, Mohlabeng, Park, Shin:
In Progress

What are the Ionization effects of boosted DM?

Can these pin-point the underlying model?

Alhazmi, Kim, Kong, Mohlabeng, Park, Shin: In Progress

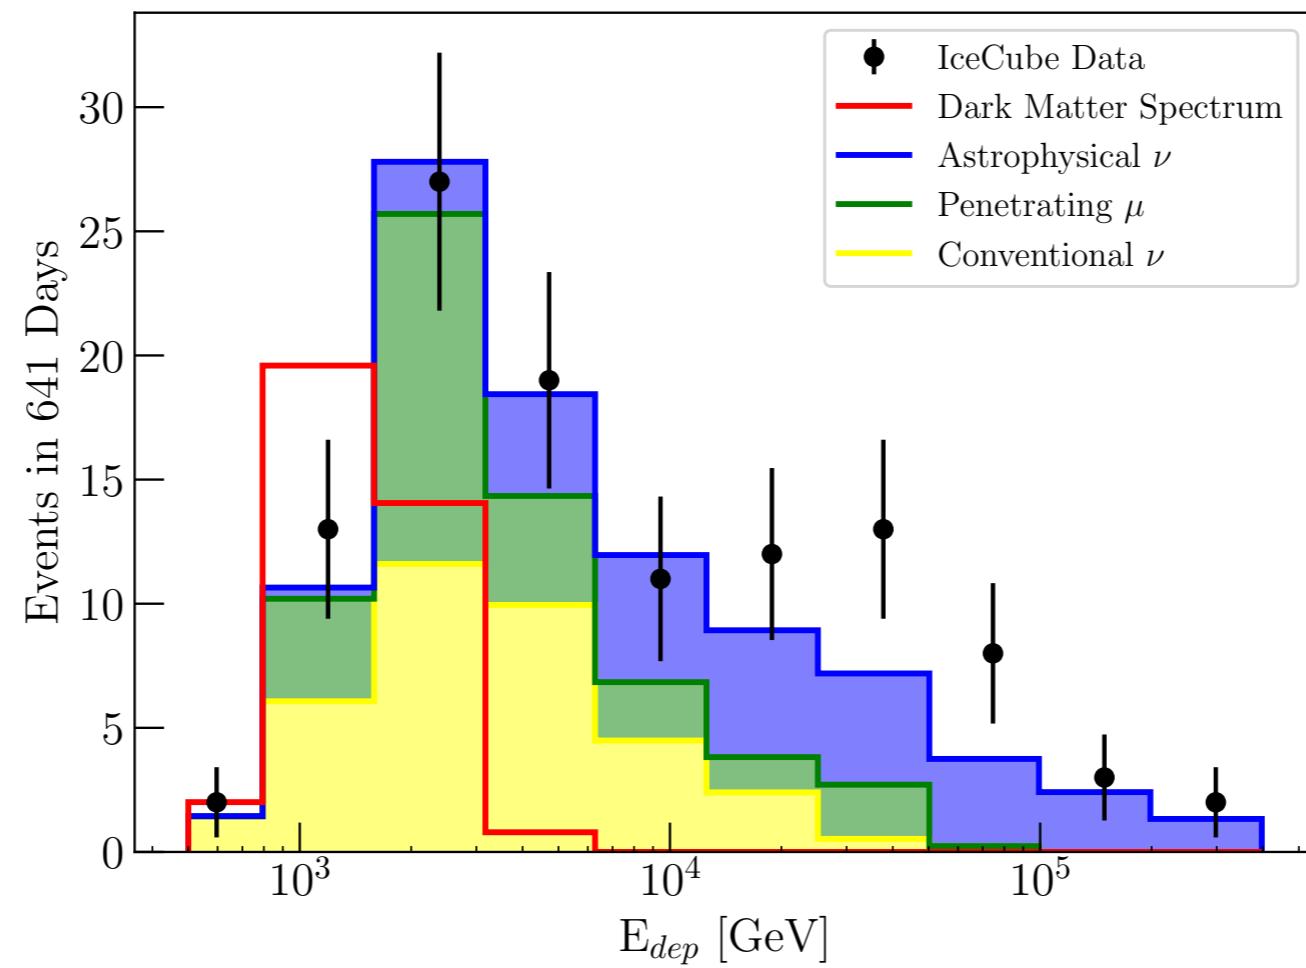

Summary

- Accelerated DM is interesting phenomenological prospect
- Can give striking signals at large volume neutrino & DM detectors
- Atomic & nuclear effects can be important for accelerated DM scattering
- Accelerated DM can open up a whole new world of possibilities**

Thank you
