What is the Zooniverse?

The world's largest and most powerful platform for people-powered research

At the Zooniverse, anyone can be a researcher

You don't need any specialised background, training, or expertise to participate.

Volunteers and professionals make real discoveries together

Zooniverse projects are constructed with the aim of converting volunteers' efforts into measurable results. They have produced a large number of published research papers, open source data sets and even scientifically significant discoveries.

Citizen Science Muon Ring Finder

Goal: Train machines to classify events and identify muon images for

- background rejection
- calibration events

Instead of solely using simulations or hard coded search algorithms we explore the power of people to get a good clean set of muon ring images for the training.

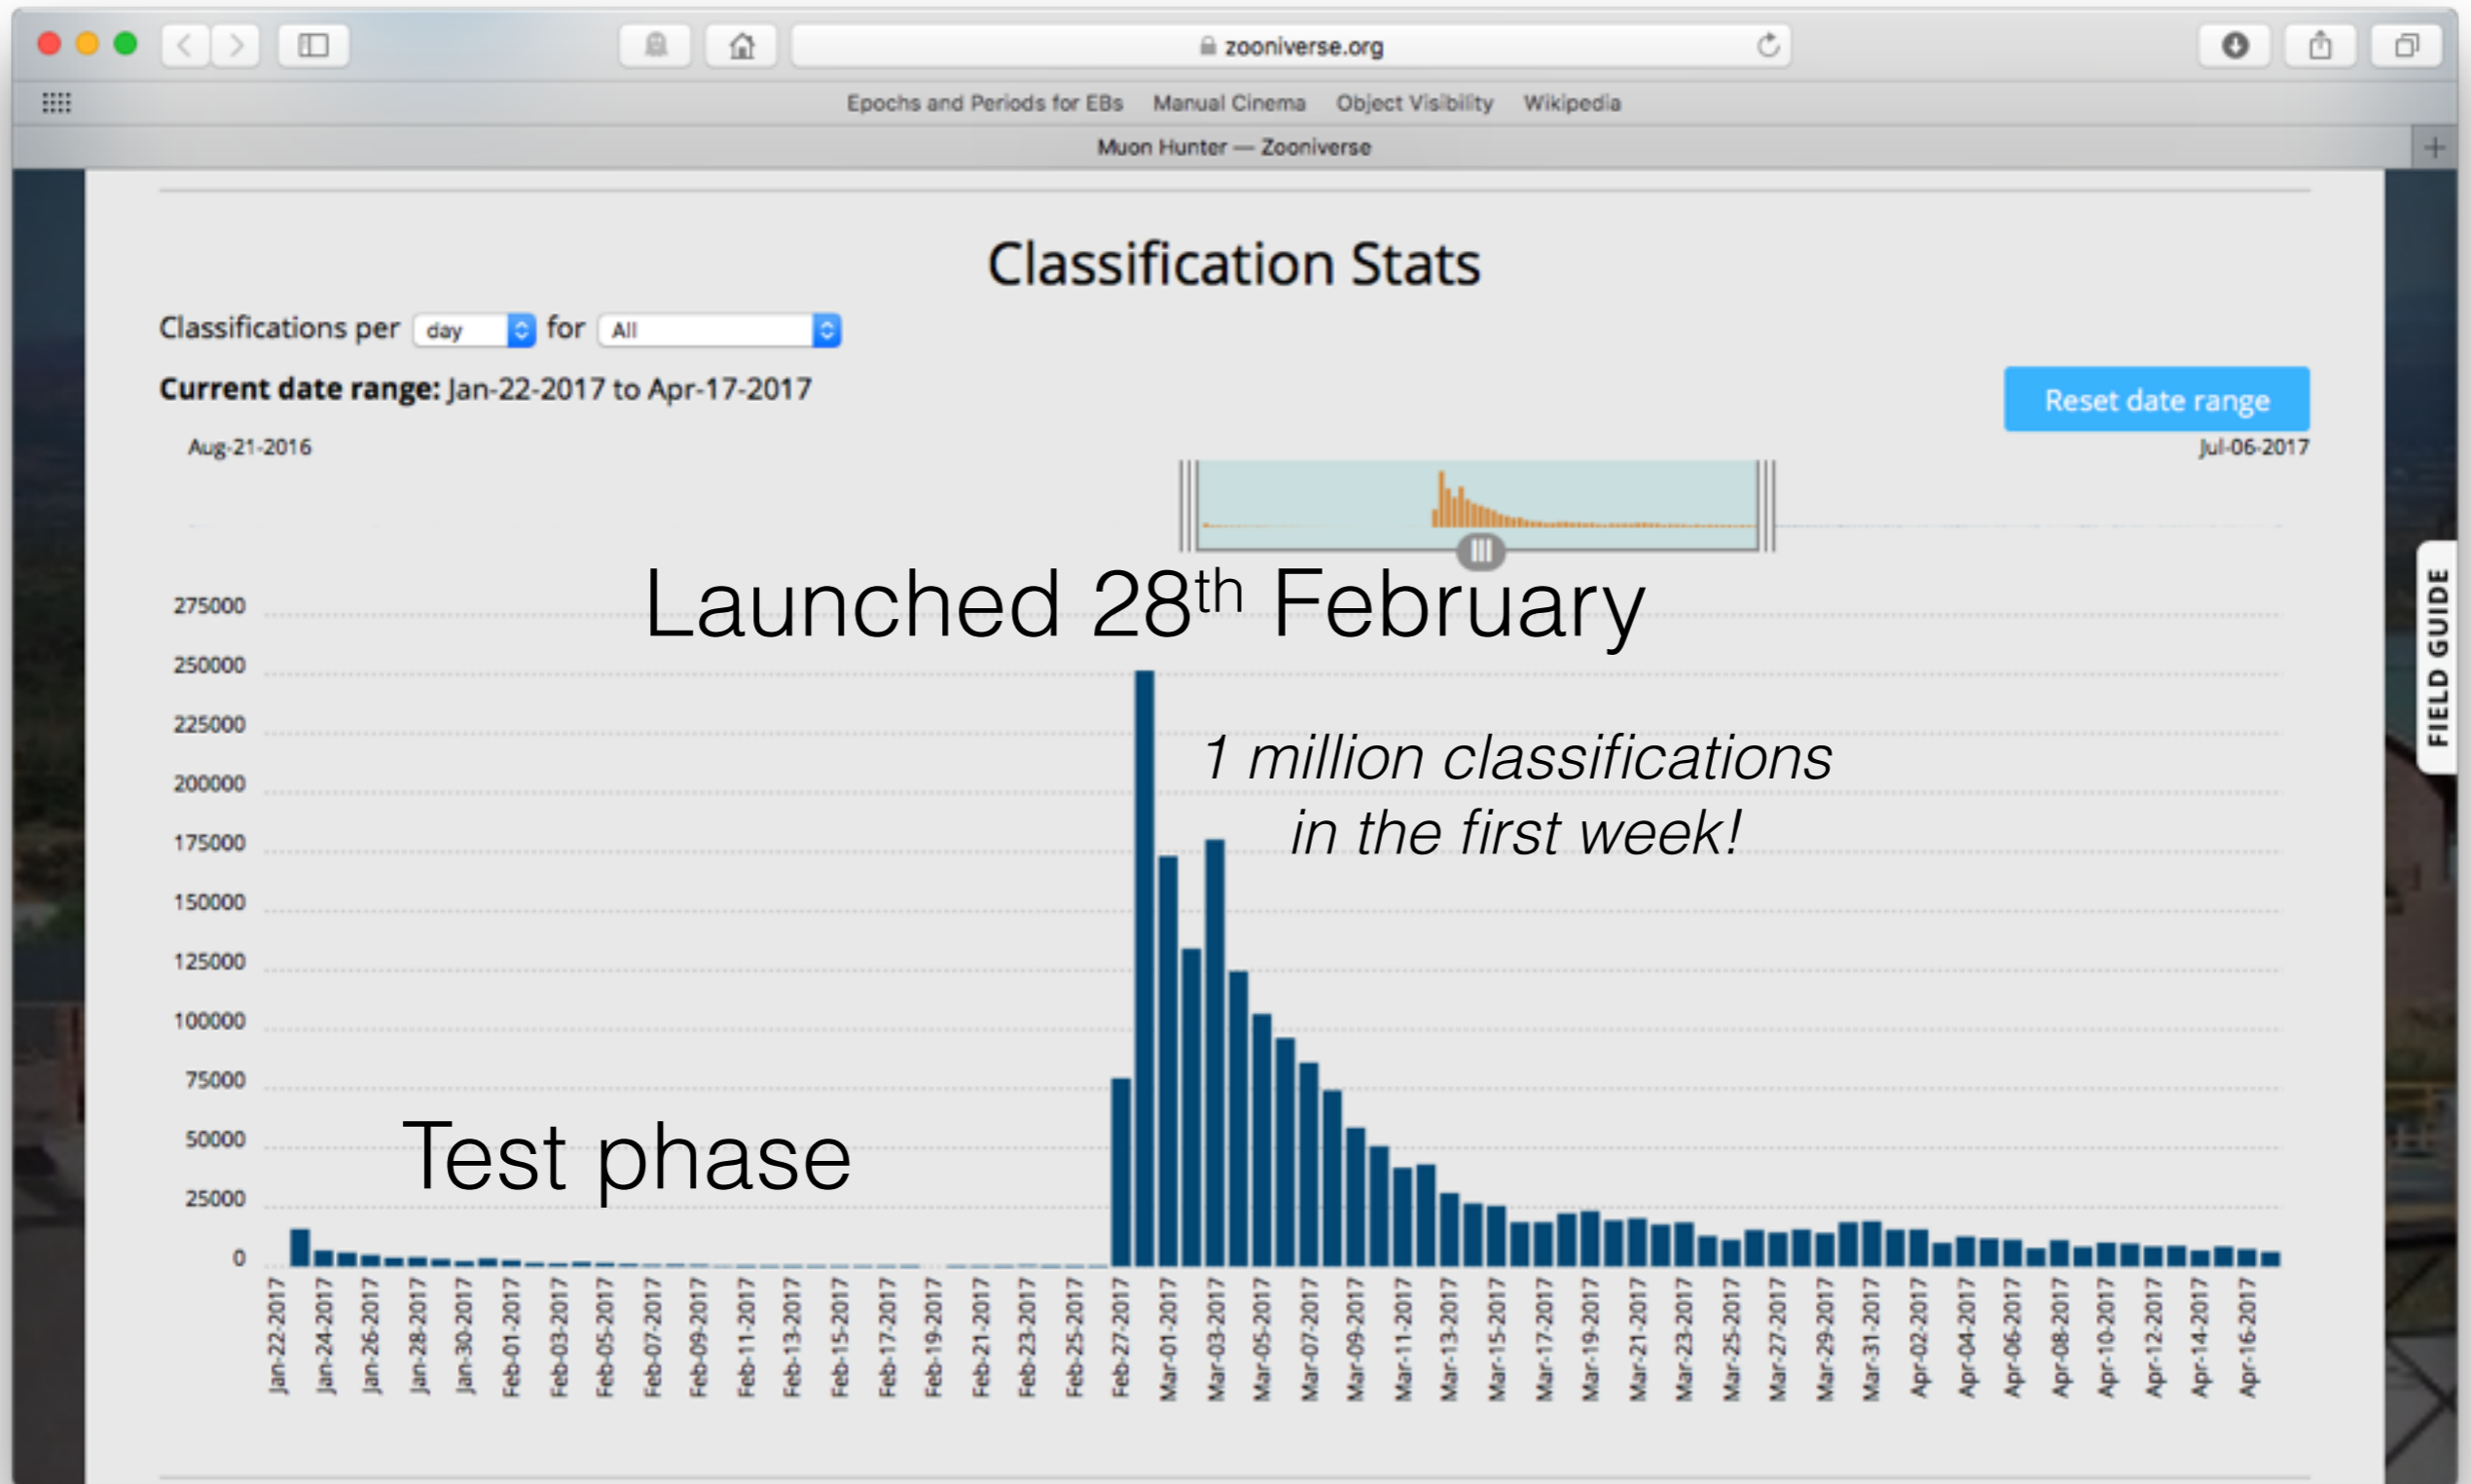

Examples & instructions are provided at the beginning

Field Guide

Retire an image when classified 15 times

Amazon Web Services outage causes widespread internet problems

5 Comments / Share / Tweet / Stumble / Email

Last Updated Feb 28, 2017 6:03 PM EST

NEW YORK -- Amazon's cloud-computing service, Amazon Web Services, experienced an outage in its eastern U.S. region Tuesday afternoon, causing unprecedented and widespread problems for thousands of websites and apps.

Amazon is the largest provider of cloud computing services in the U.S. Beginning around midday Tuesday on the East Coast, one region of its "S3" service based in Virginia began to experience what Amazon, on its service site, called "increased error rates."

In a statement, Amazon said as of 4 p.m. E.T. it was still experiencing "high error rates" that were "impacting various AWS services."

"We are working hard at repairing S3, believe we understand root cause, and are working on implementing what we believe will remediate the issue," the company said.

But less than an hour later, an update offered good news: "As of 1:49 PM PST, we

Some affected websites had fun with the crash, treating it like a snow day:

Muon Hunter: a Zooniverse project

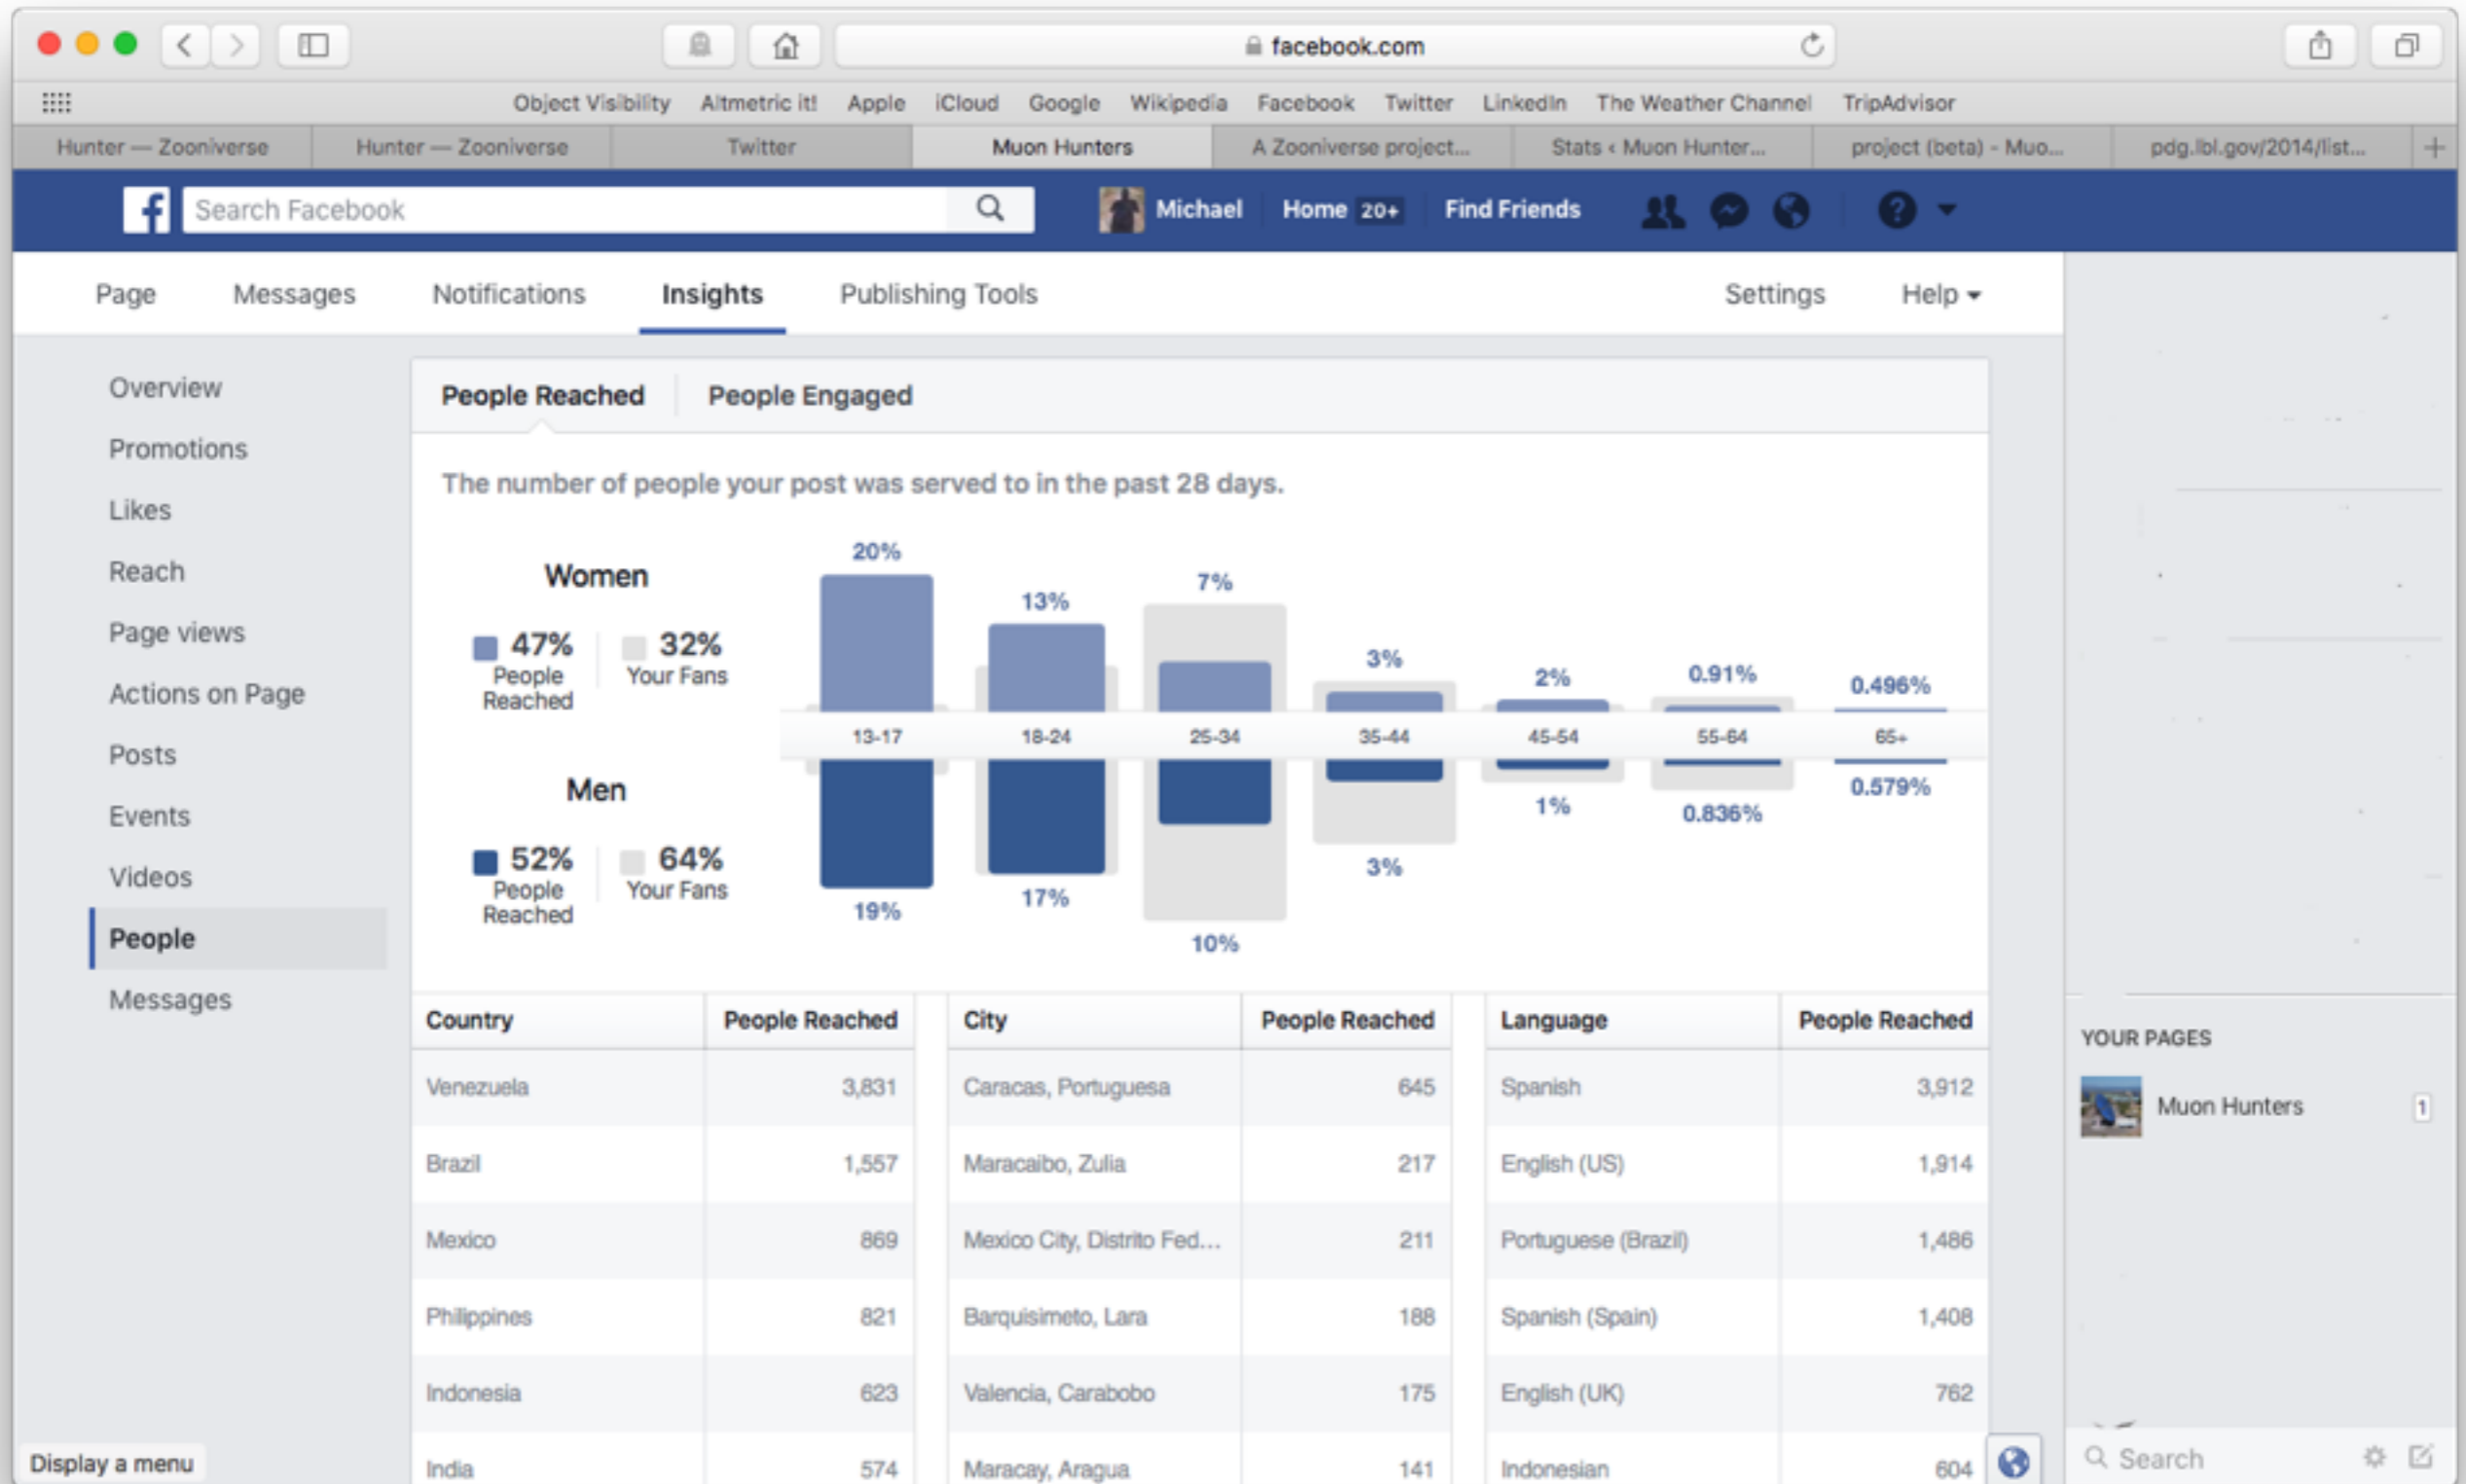

***Astronomers using the
VERITAS telescopes to
detect some of the
highest-energy photons in
the Universe need your
help!***

Gamma-rays originate in astrophysical environments like supernova explosion blast waves, or jets streaming from active galaxies at close to light speed. Muons (a particle like an electron, only heavier!) are a prominent background contaminant when observing these gamma-rays on Earth. They leave a distinctive ring-like shape making them obvious to the human eye, but incomplete or truncated rings can appear very gamma-ray-like to automatic analysis algorithms. We need your help to identify camera images that contain muon rings so we can teach computers to better identify such images and efficiently filter out those pesky muons that are masquerading as gamma rays.

FIELD GUIDE

zooniverse.org

Epochs and Periods for EBs Object Visibility Wikipedia

Muon Hunter — Zooniverse

million muons to pass through every minute.

Each image is about a 20ns exposure, which means we expect about 0.02 muons every ns to be the average rate. The probability of seeing 1, 2, or 3, etc muons is described by something called a Poisson distribution which relates the average rate of an event to the likelihood of seeing it. If 97.7% of the time we see no muons, 2.2% we see 1 muon, 0.02% of the time we see 2 muons, 0.0002% (or only 1 in 5,000) times we see three muons and so on.

In reality that is an oversimplification because the arrival rate of muons is not completely random: the cosmic rays arrive randomly, the air showers they then create contain many thousands of muons arriving just a few nanoseconds apart (and not minutes) spread over an area of a few thousand square metres. Also other particles will create similar rings, e.g. when a muon decays it creates an electron which will produce a similar ring to its parent muon and you will see both rings in the image just slightly separated.

But the general conclusion still holds: most images will contain no muons, a good many will contain one muon, a very few will contain two, and it becomes increasingly rarer still to see any more than that in the same image. We have many hundreds of thousands of images in our dataset so even some rare events have a chance of turning up, such as here.

 BrianaG @BrianaG

I am so glad to have seen someone use the Poisson distribution, @mkdaniel I thought I'd never see it again after college!

Glad I didn't have to sort 5000 images to see one, though. Thanks @Huskynator for flagging this!

FIELD GUIDE

~1 month after launch

The screenshot shows the Zooniverse Muon Hunter website interface. At the top, the navigation menu includes MUON HUNTER, ABOUT, CLASSIFY, TALK, COLLECT, and BLOG. The main content area displays the following statistics:

- Feb-28-2017 (Launch Date)
- 5,801 Registered Volunteers (highlighted with a purple box)
- 187 Classifications Yesterday

Below these statistics, the text "Live Workflows" is displayed. A purple arrow points from the "5,801 Registered Volunteers" box to a purple box containing the text "VERITAS collaboration O(100) members".

On the left side, there is a section titled "Find those muons!" with the following details:

- Retirement limit: 15
- Images retired: 135,009 / 137,515
- Classifications: 2,146,753 / 2,062,725
- ETC* 0 days

A large blue circular progress indicator shows "100% Complete".

At the bottom, a disclaimer reads: "*Estimated time to completion is based on the classification rate for the past 14 days and may be incorrect due to the way we currently report the data, or unavailable for some workflows."

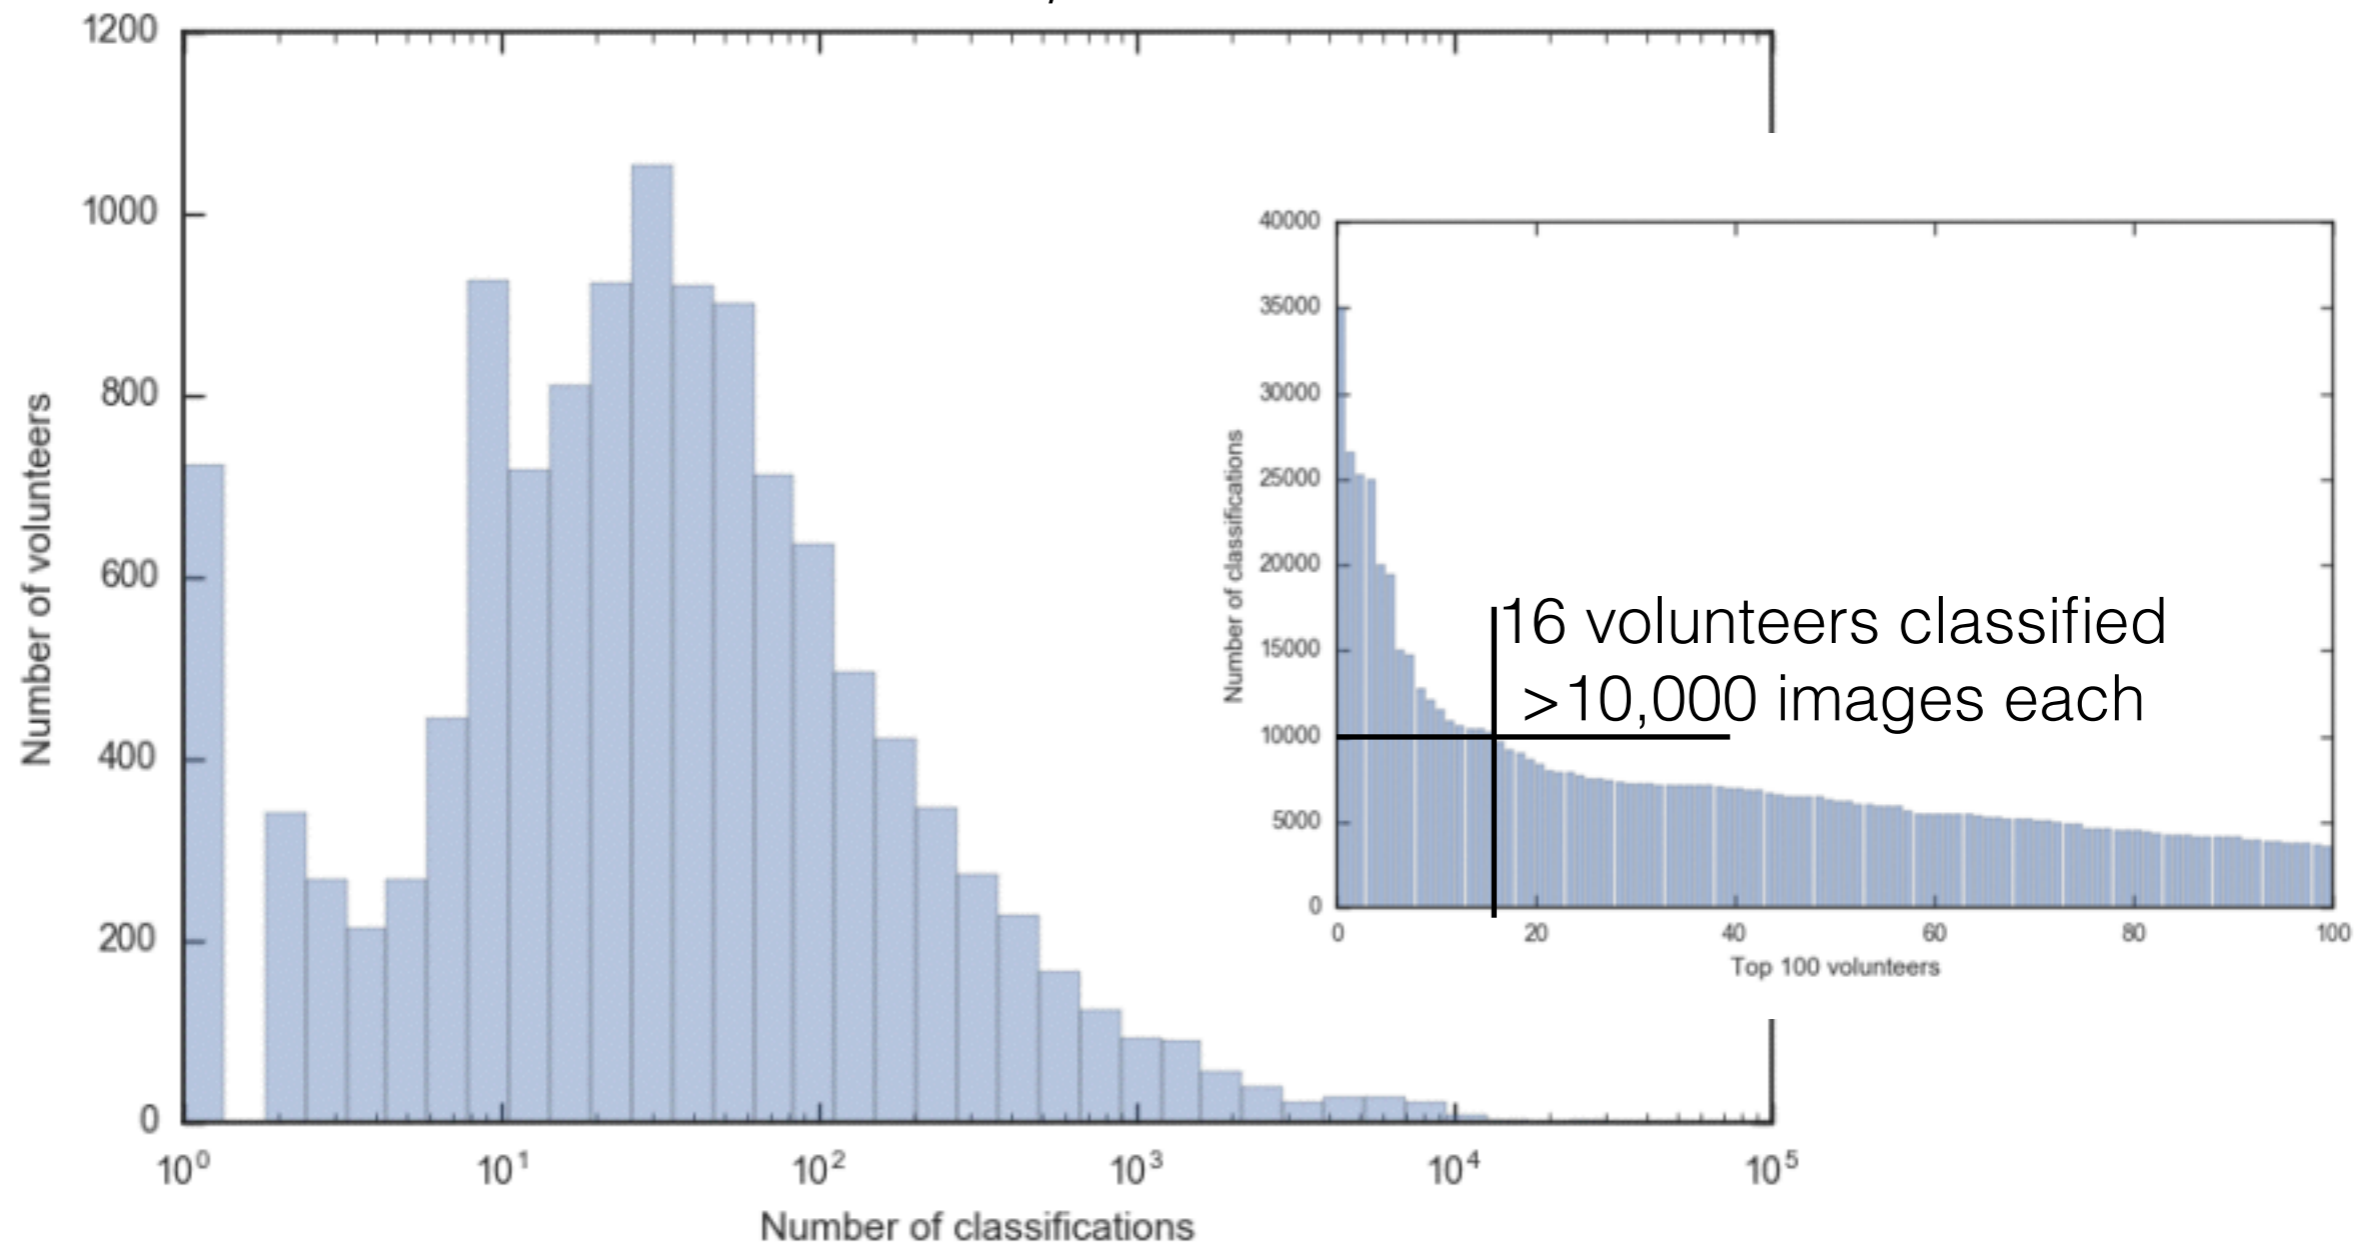

A vertical "FIELD GUIDE" button is visible on the right side of the page.

The median number of image classifications per volunteer is 30

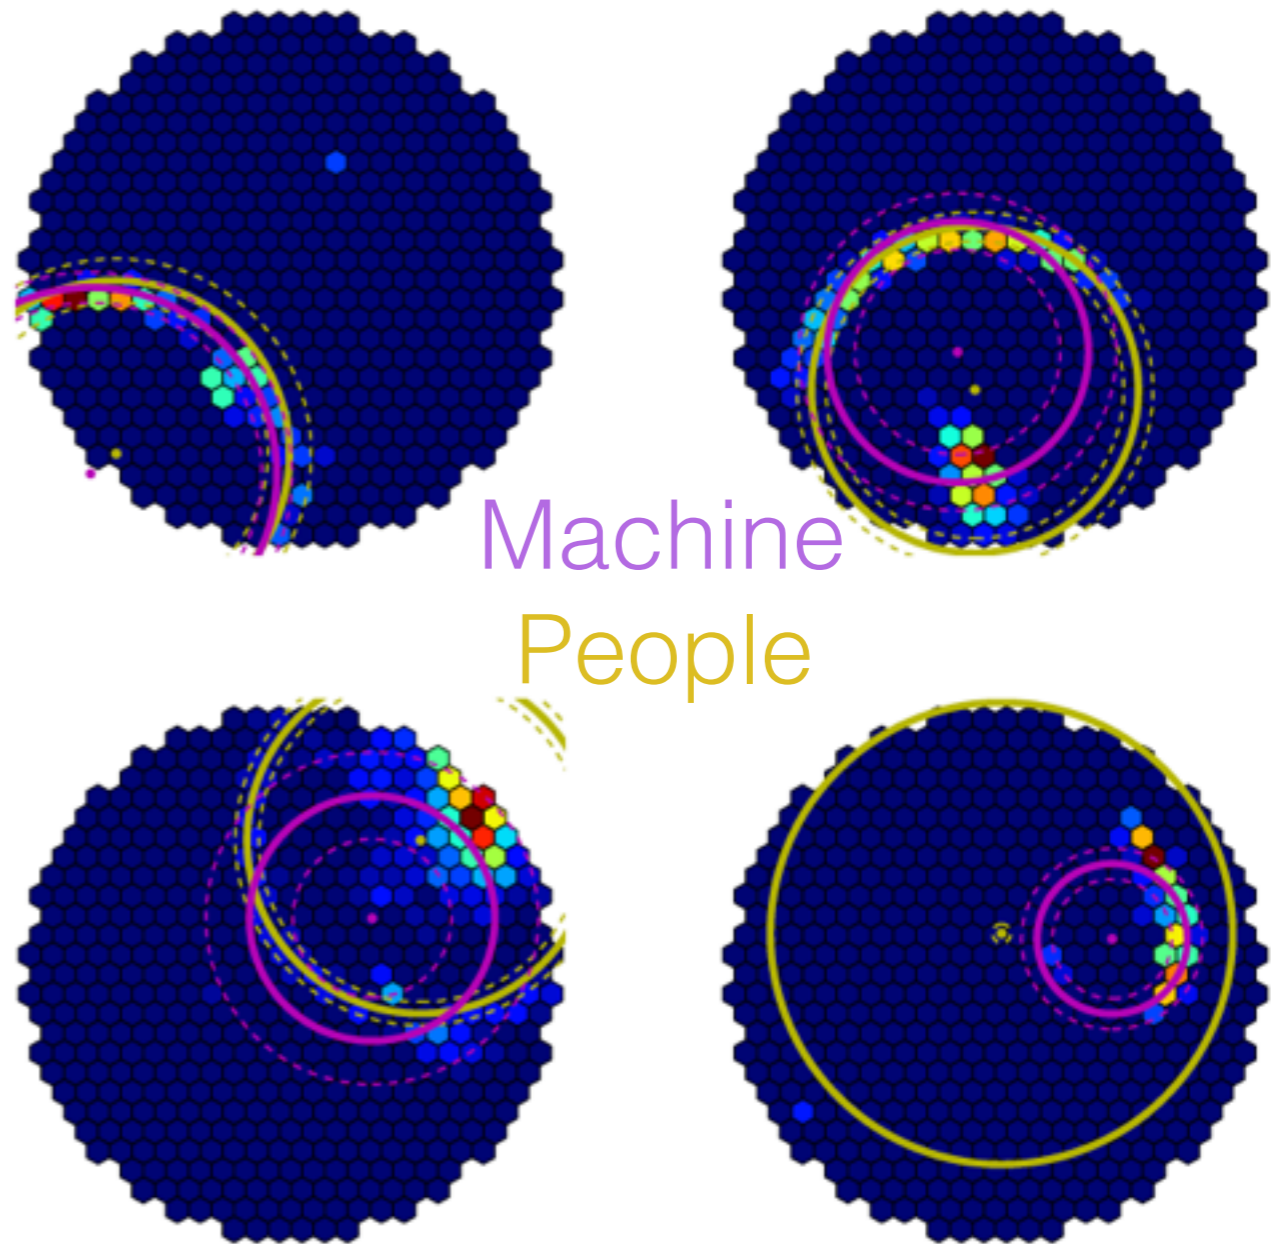

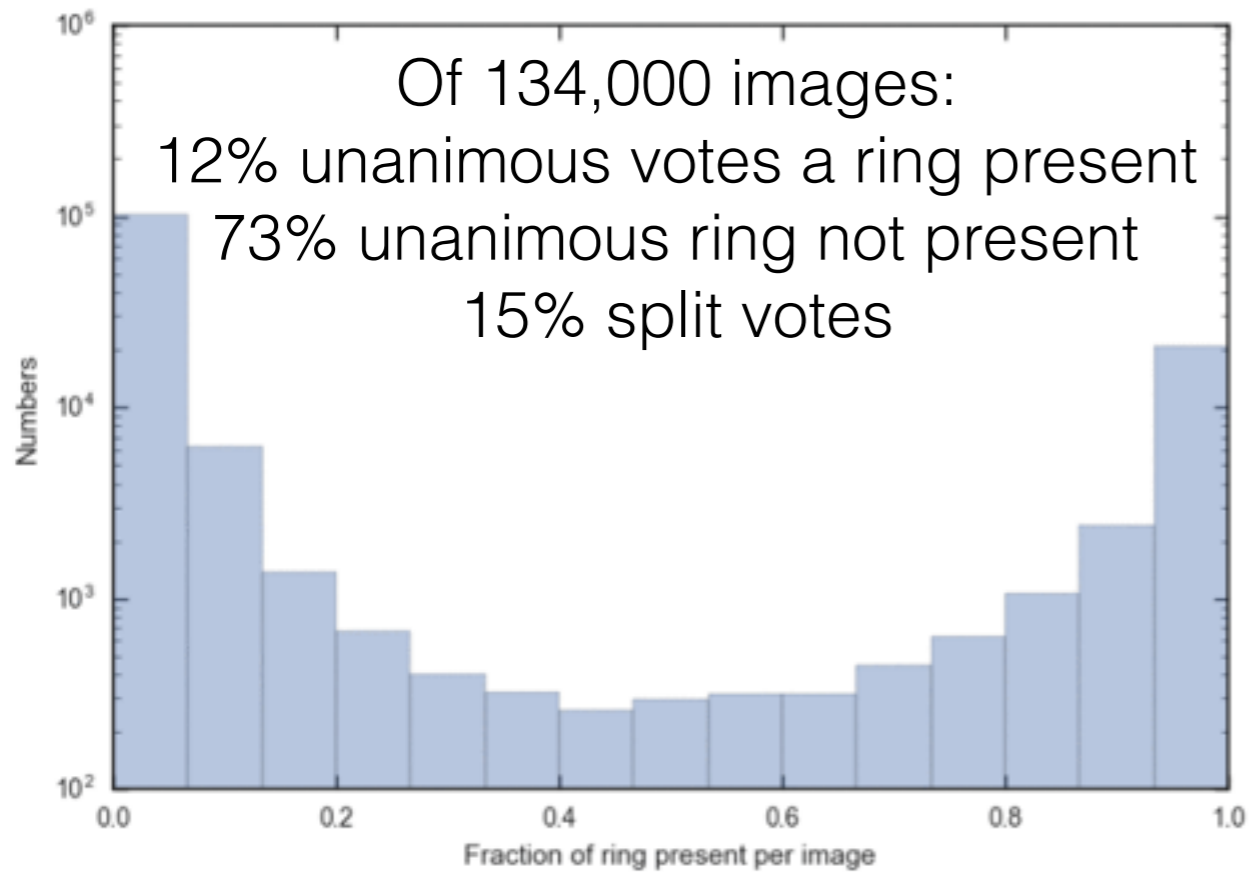

Gini co-efficient = 0.83 (0 = equally shared)
(1 = one dominates)

Most have less time to commit, but contribute what they can.
A few have a lot of time/interest to devote

<https://muonhunterblog.wordpress.com/2017/05/24/a-quick-look-at-the-volunteer-input/>

Treating all images with $\geq 9/15$ votes for ring as muon events
 trained a convolutional neural network model with score of 0.97
 cf previous algorithm score of 0.95

Summary

- Citizen science is a great resource for both outreach and practical science.
- People are willing (& able) to look through a mountain of data in the search for circles
 - ➔ Having a simple, clearly defined project task helped a lot with the success of the project.
- They are also likely to find other interesting things when parsing that much data
 - ➔ Feeds into what projects to do next...
