Galactic Halo Bubbles

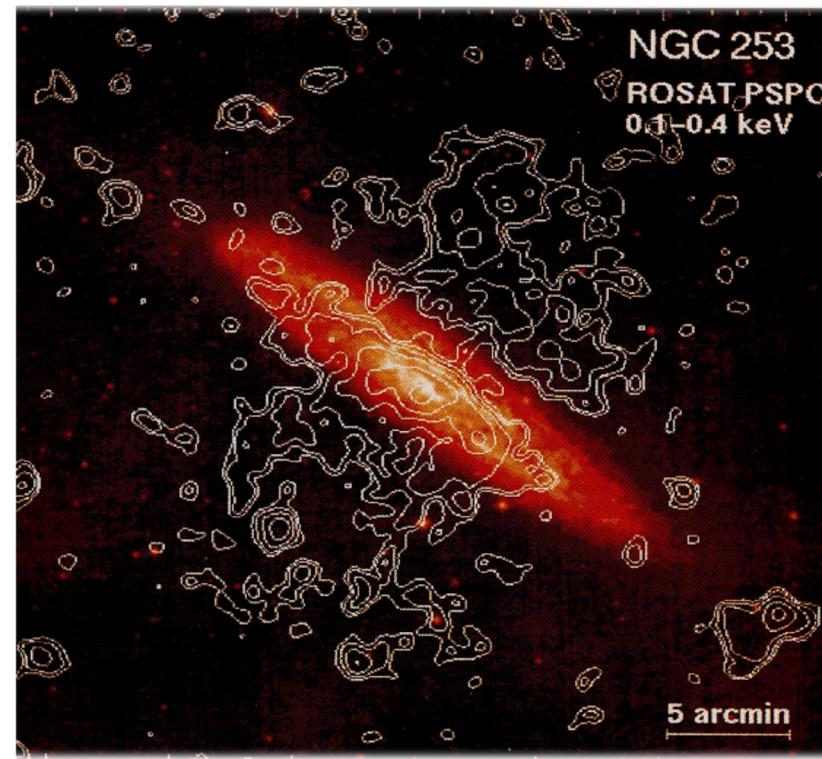

10^{56} erg in X-rays
Total energy 10^{54-55} erg in disc

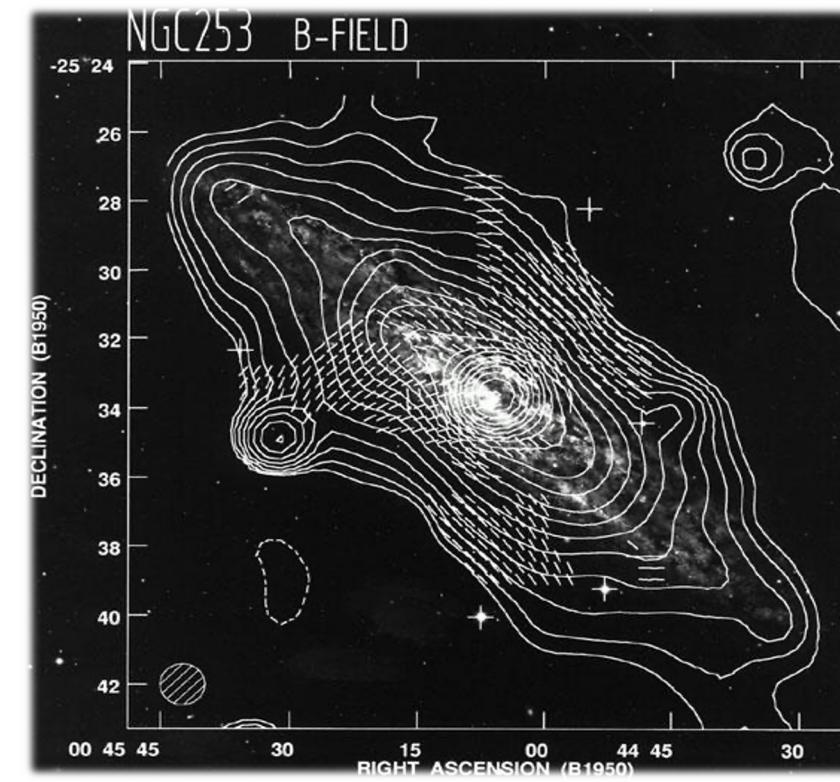

Predehl, P., Sunyaev, R.A., Becker, W. et al. Detection of large-scale X-ray bubbles in the Milky Way halo. Nature 588, 227–231 (2020). <https://doi.org/10.1038/s41586-020-2979-0>

Large scale structures = large scale fields

(Pietsch et.al 1996)

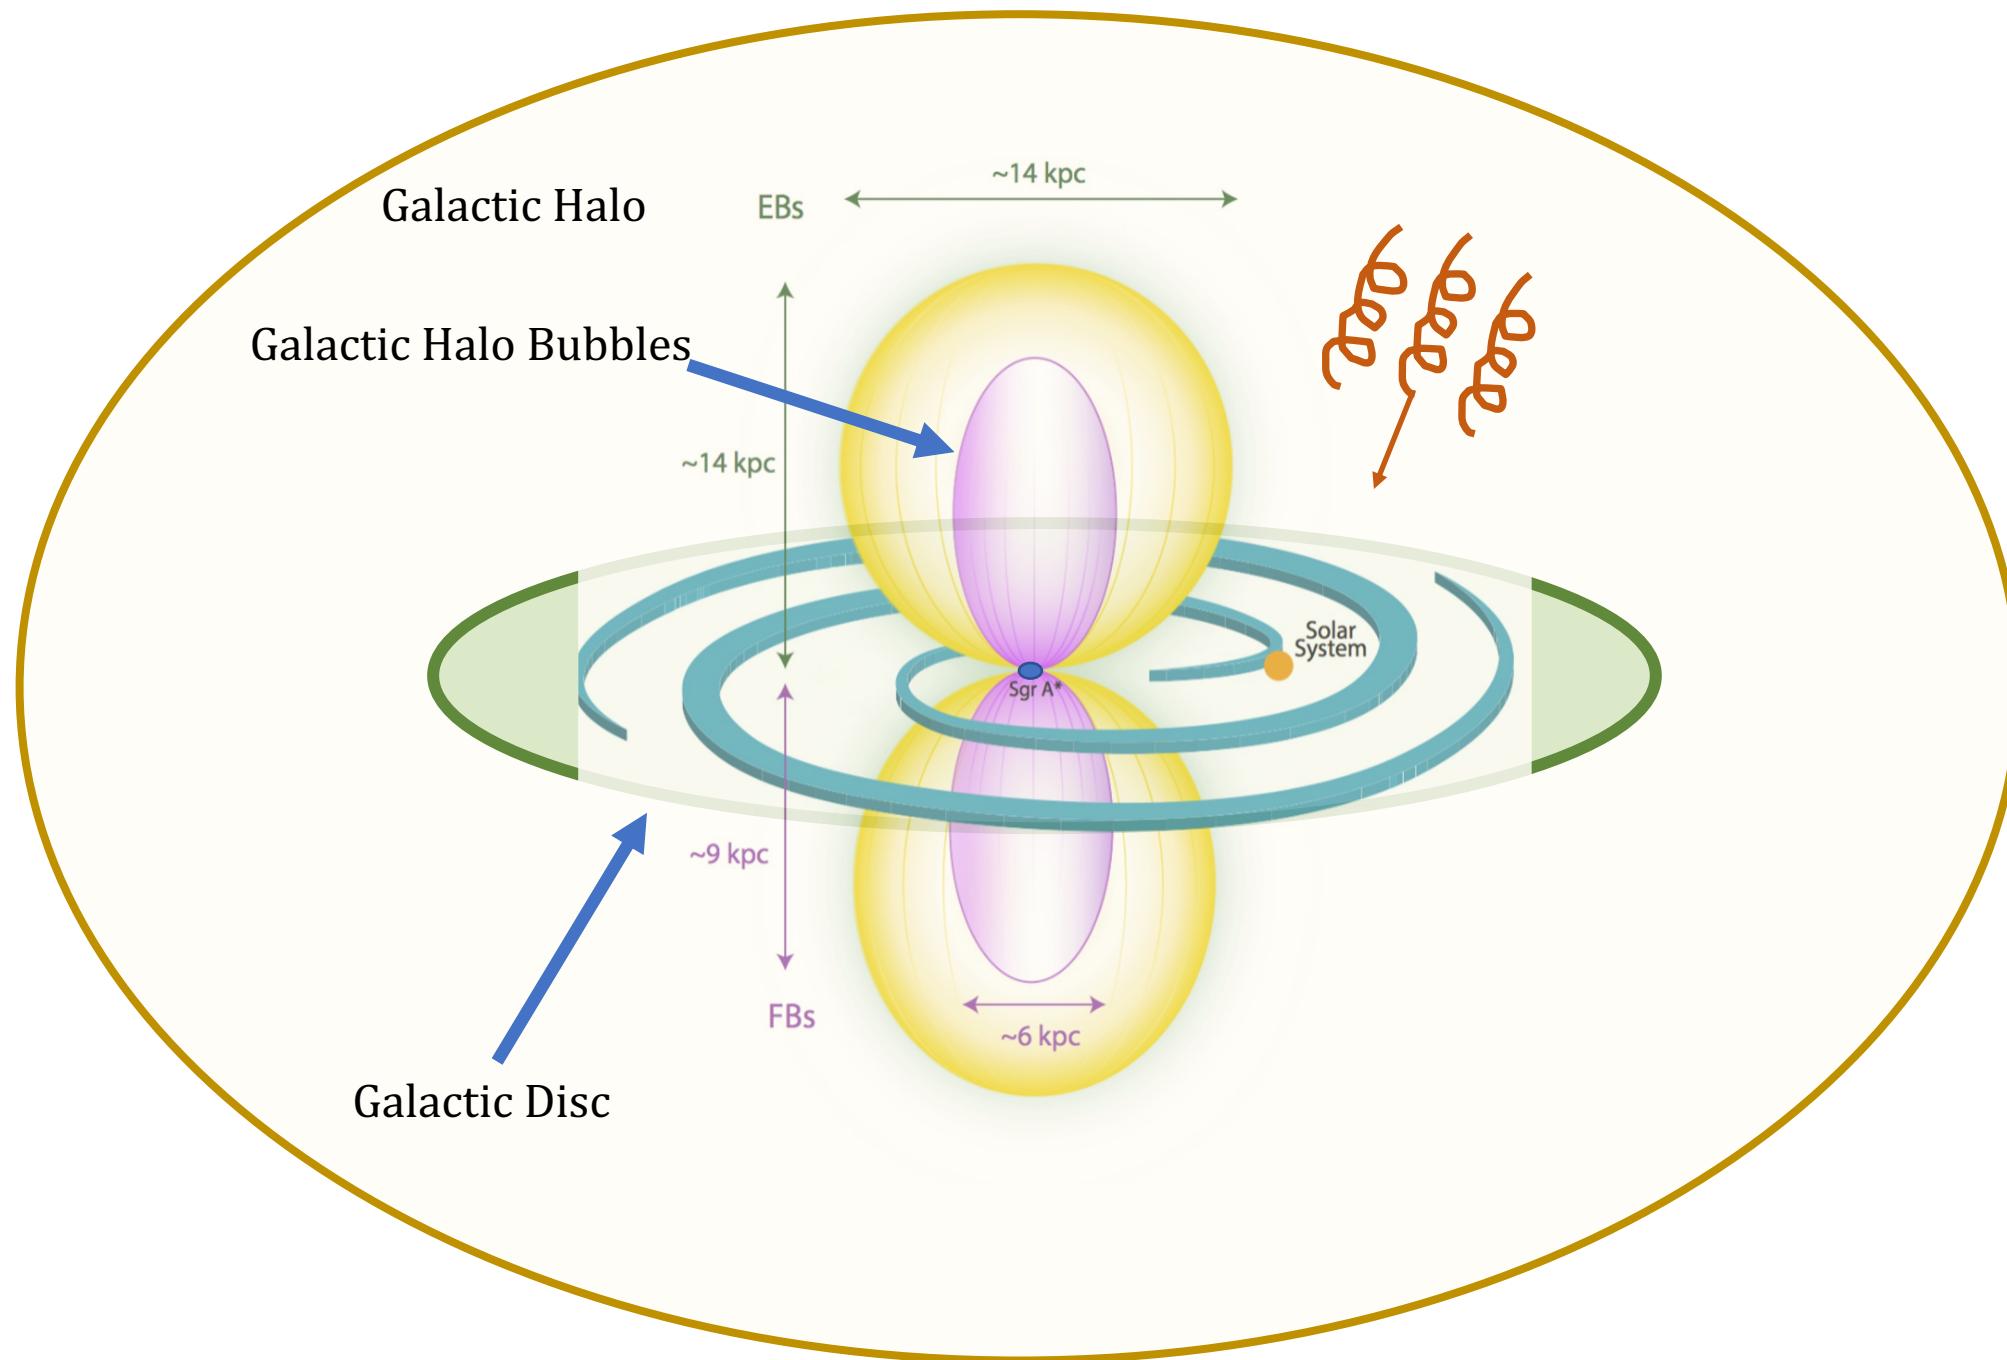

(Beck et.al 1994)

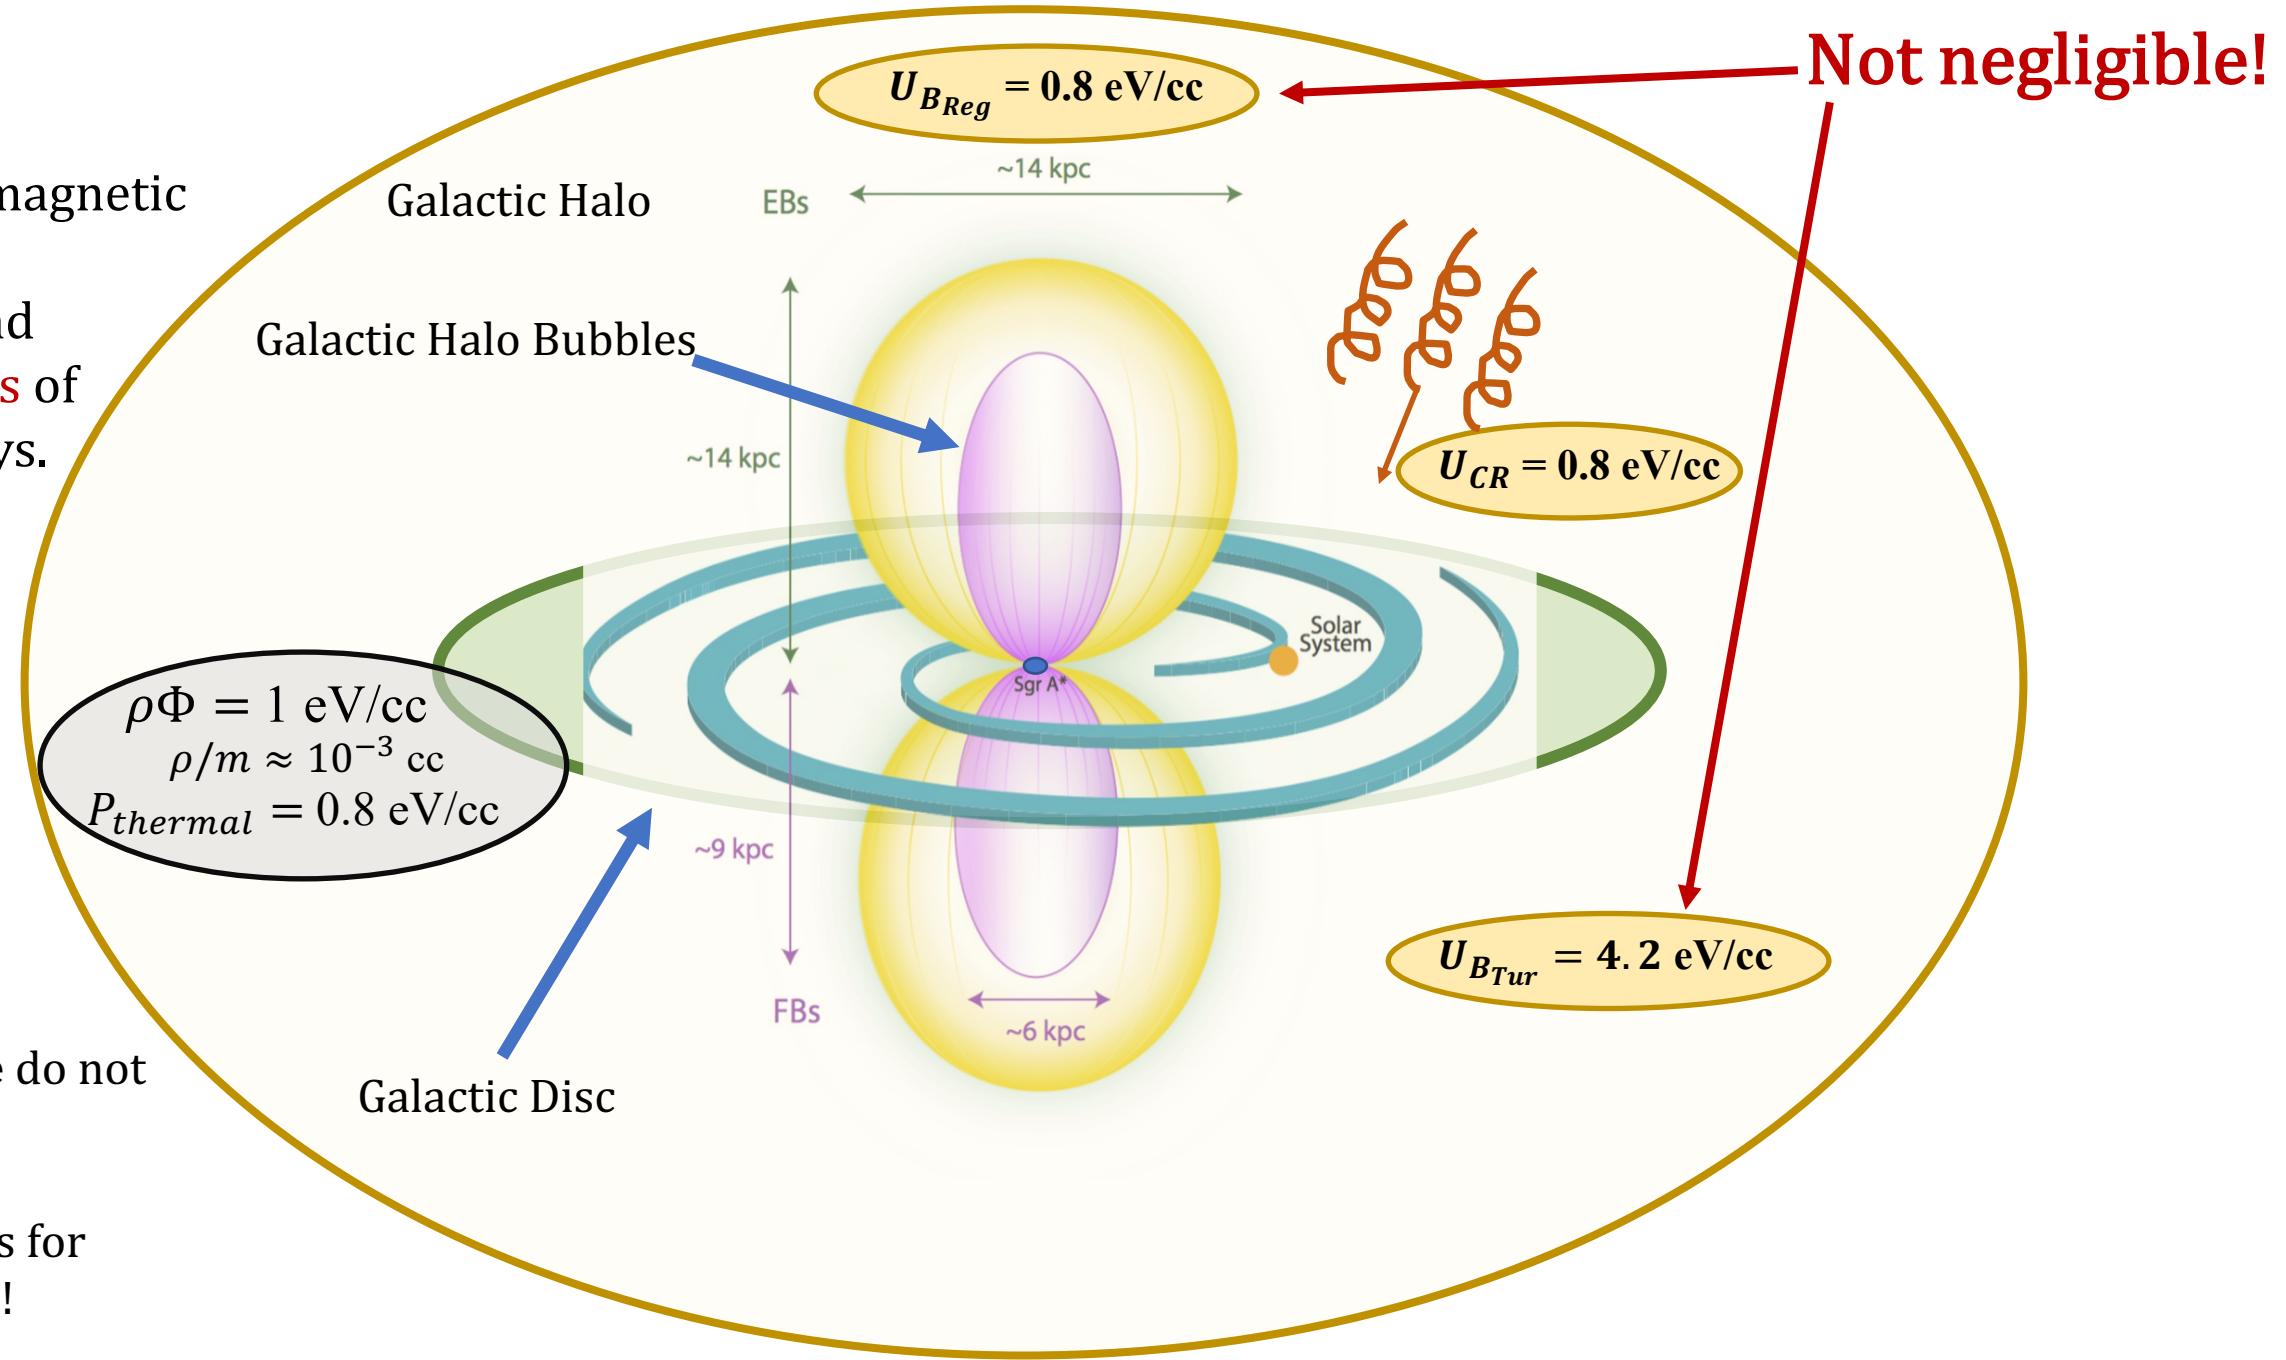

Total radio intensity (*contours*) and magnetic field orientation of [NGC 253](#).

Milky way is not a starburst galaxy yet it has outflow!

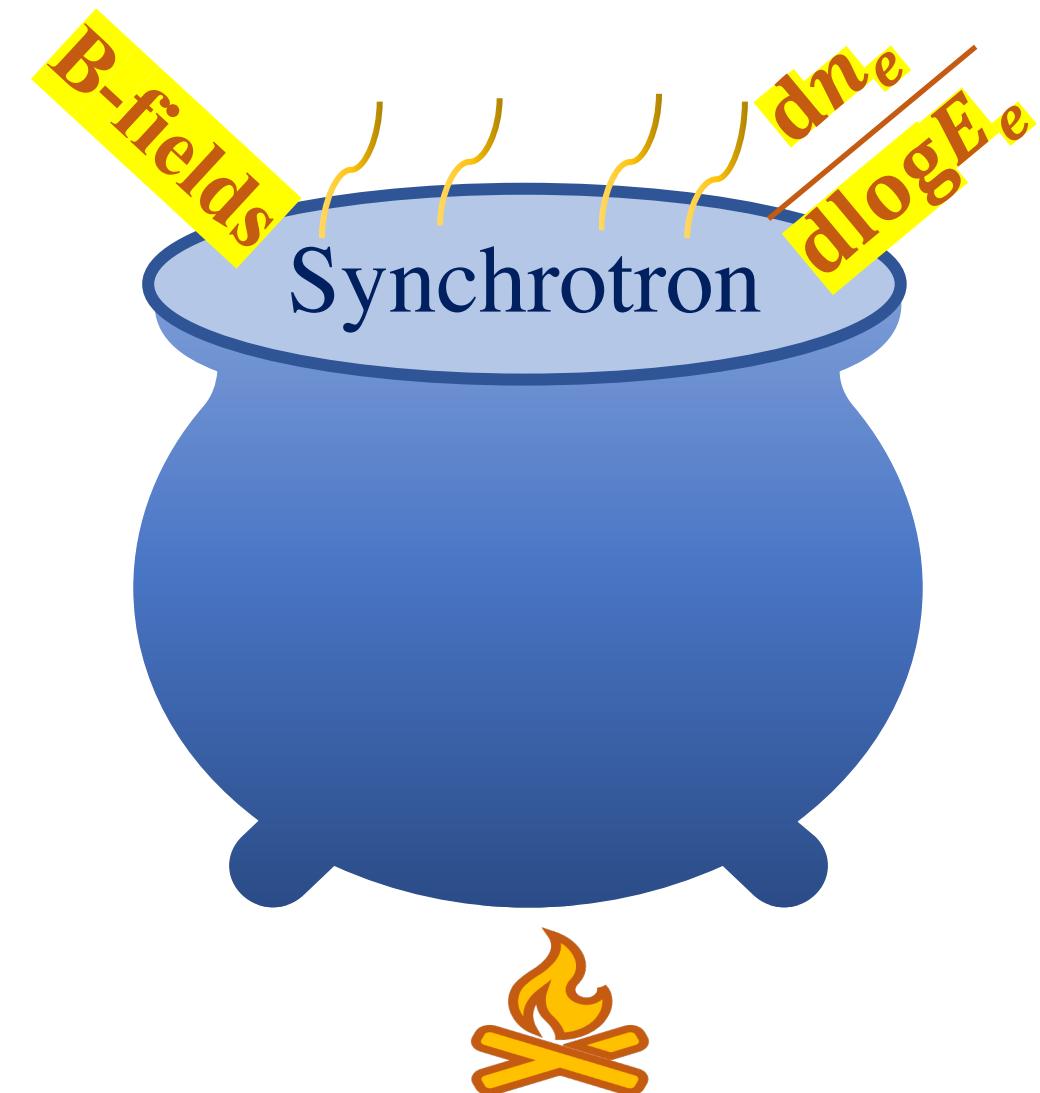

We need magnetic fields to understand **deflections** of cosmic rays.

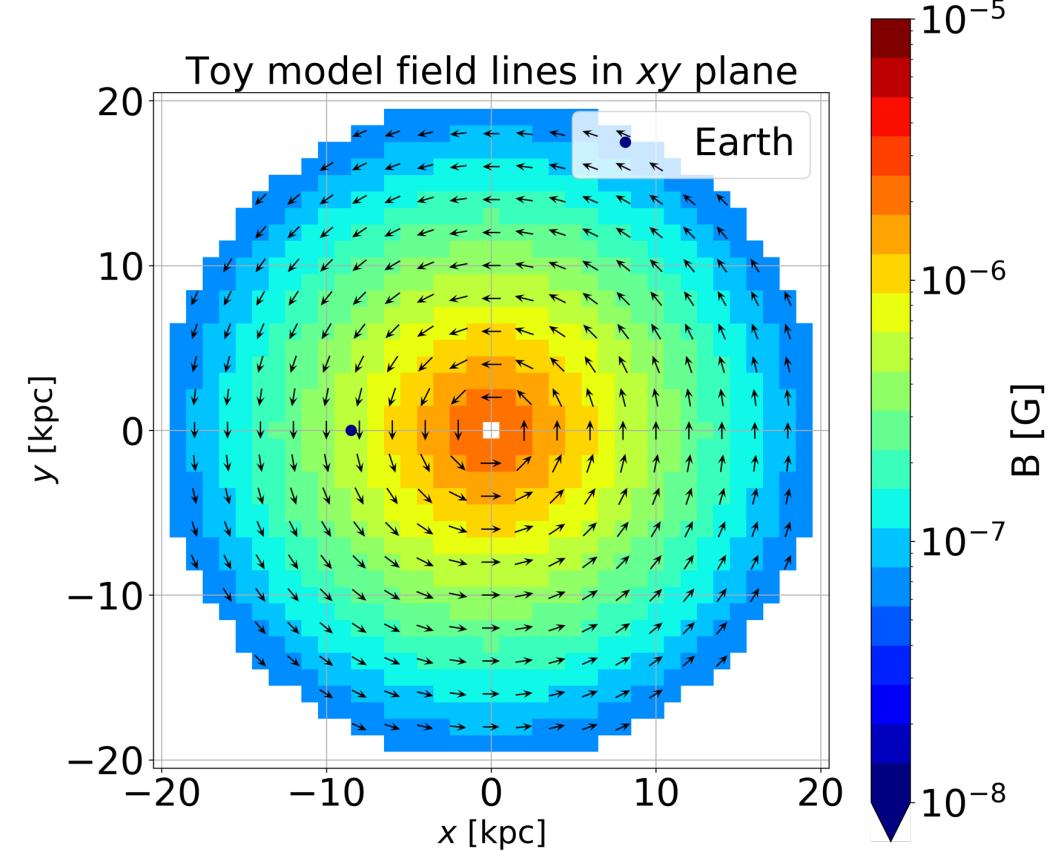

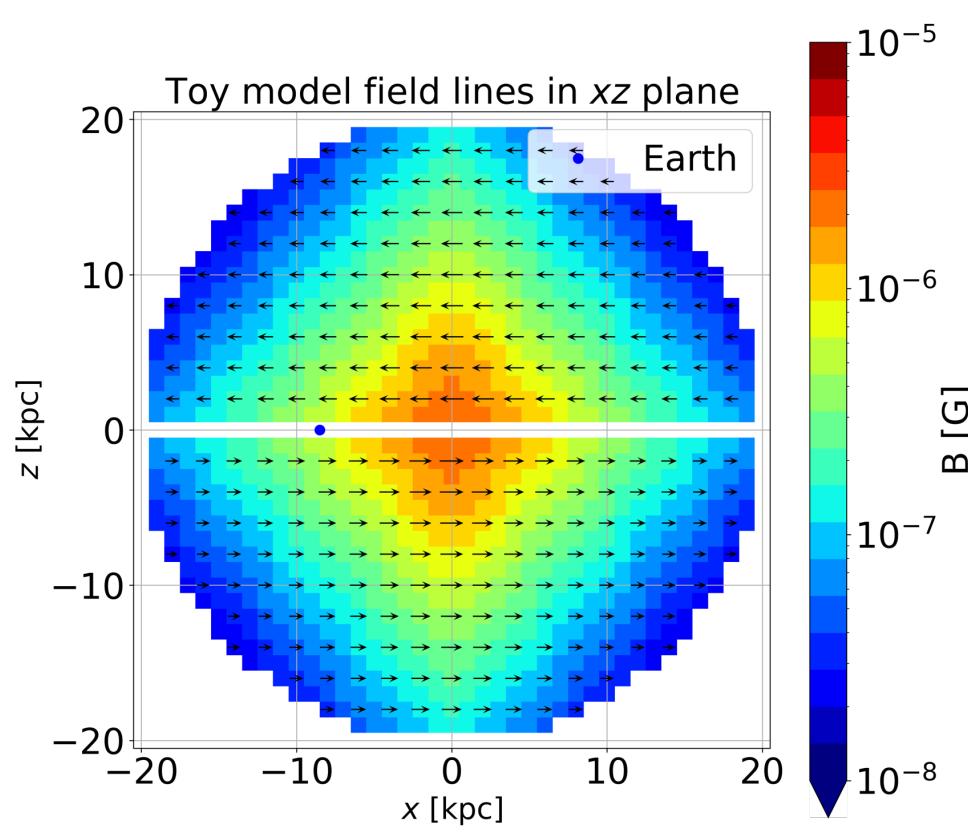

Note: We do not have any accurate estimates for the Halo !

Probing magnetic fields with synchrotron radiation

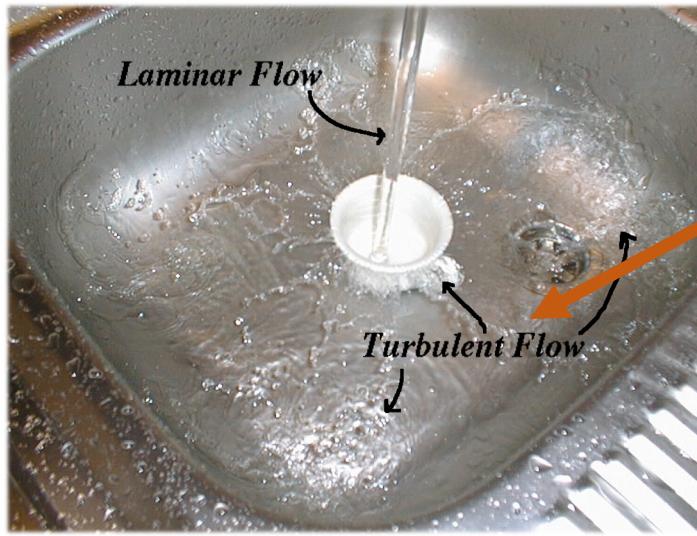

Toy Model – Structured fields

$$B_{\text{tor}} = B_{\text{str}} e^{(-|z|/Z_{\text{mag}})} e^{(-z_{\min}/|z|)} e^{(-|r|/R_{\text{mag}})}$$

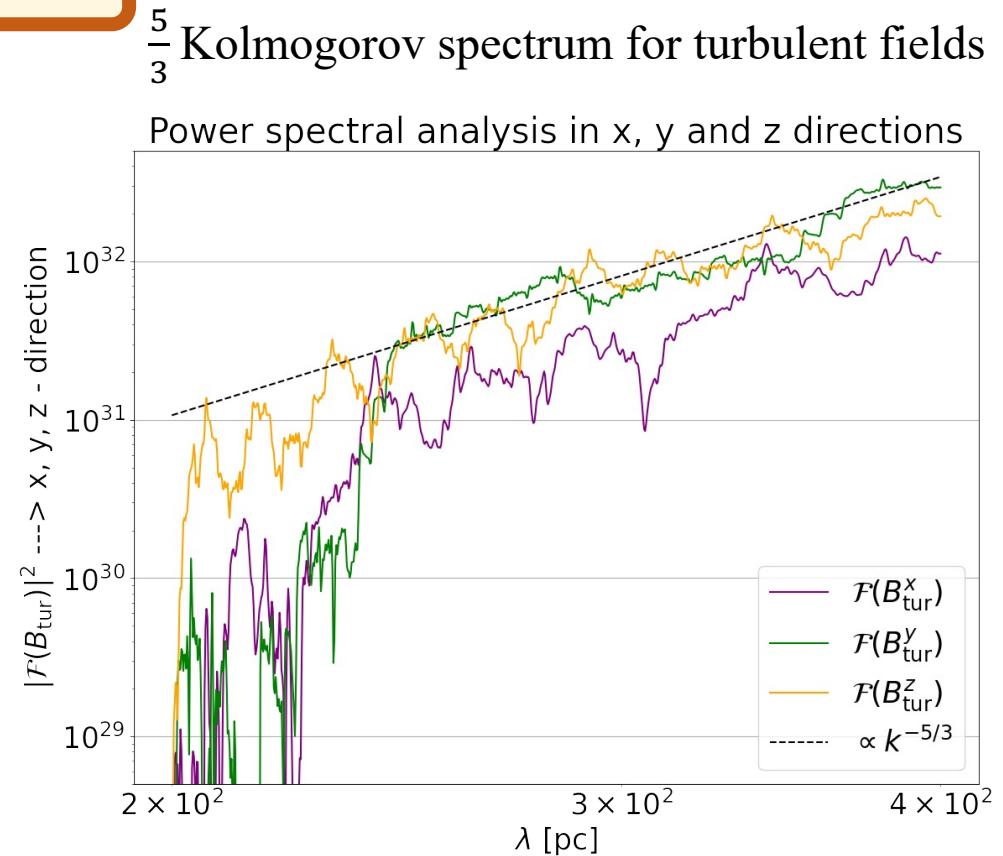

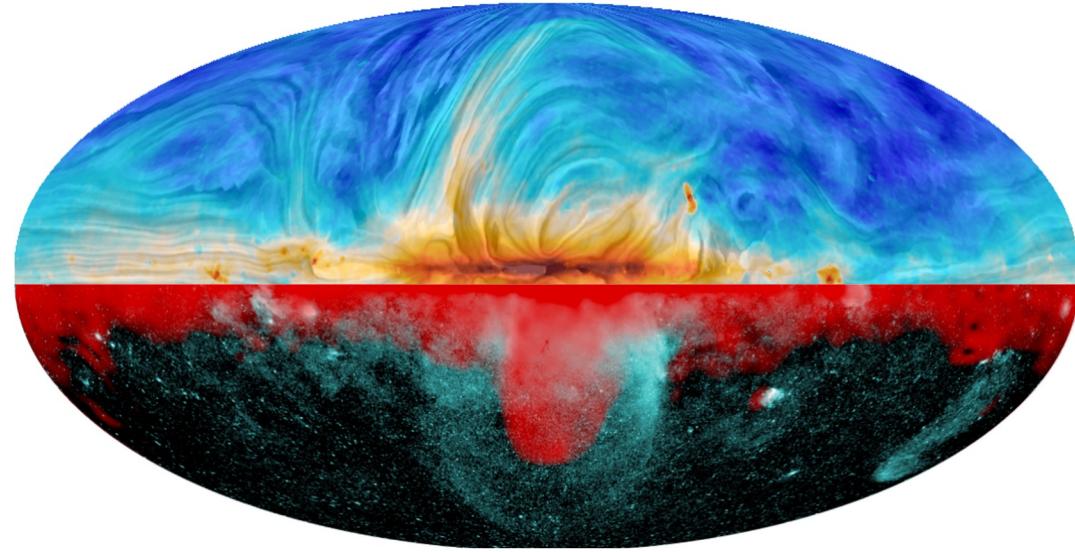

$$R_{\text{mag}} \text{ & } Z_{\text{mag}} = 5 \text{ kpc and } 6 \text{ kpc } B_{\text{str}} = 3.96 \mu\text{G}$$

Toy Model –Turbulent fields

Outflow induces turbulent fields

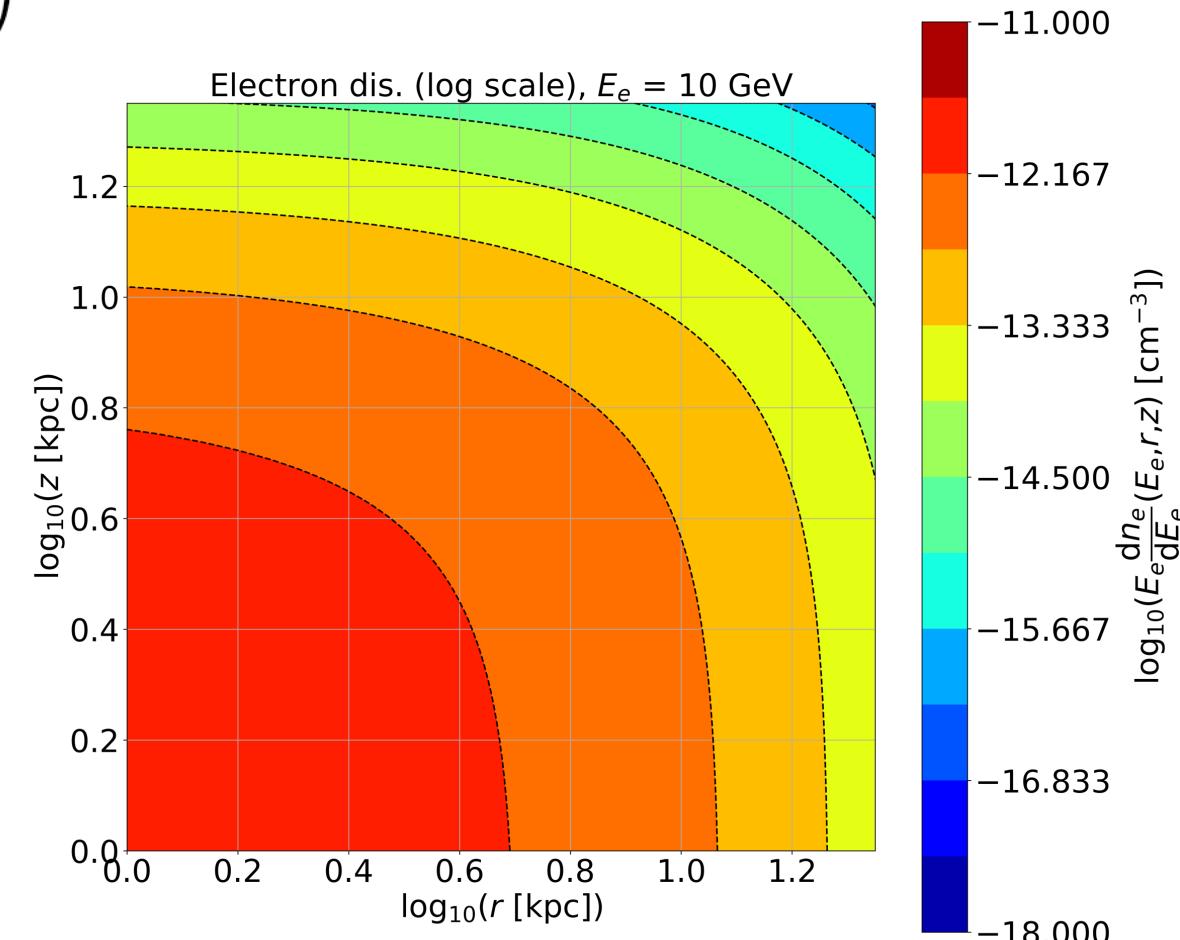

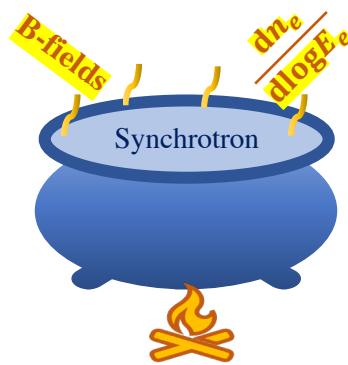

Almost same power in each mode

Toy Model – non-thermal electron distribution at 10 GeV

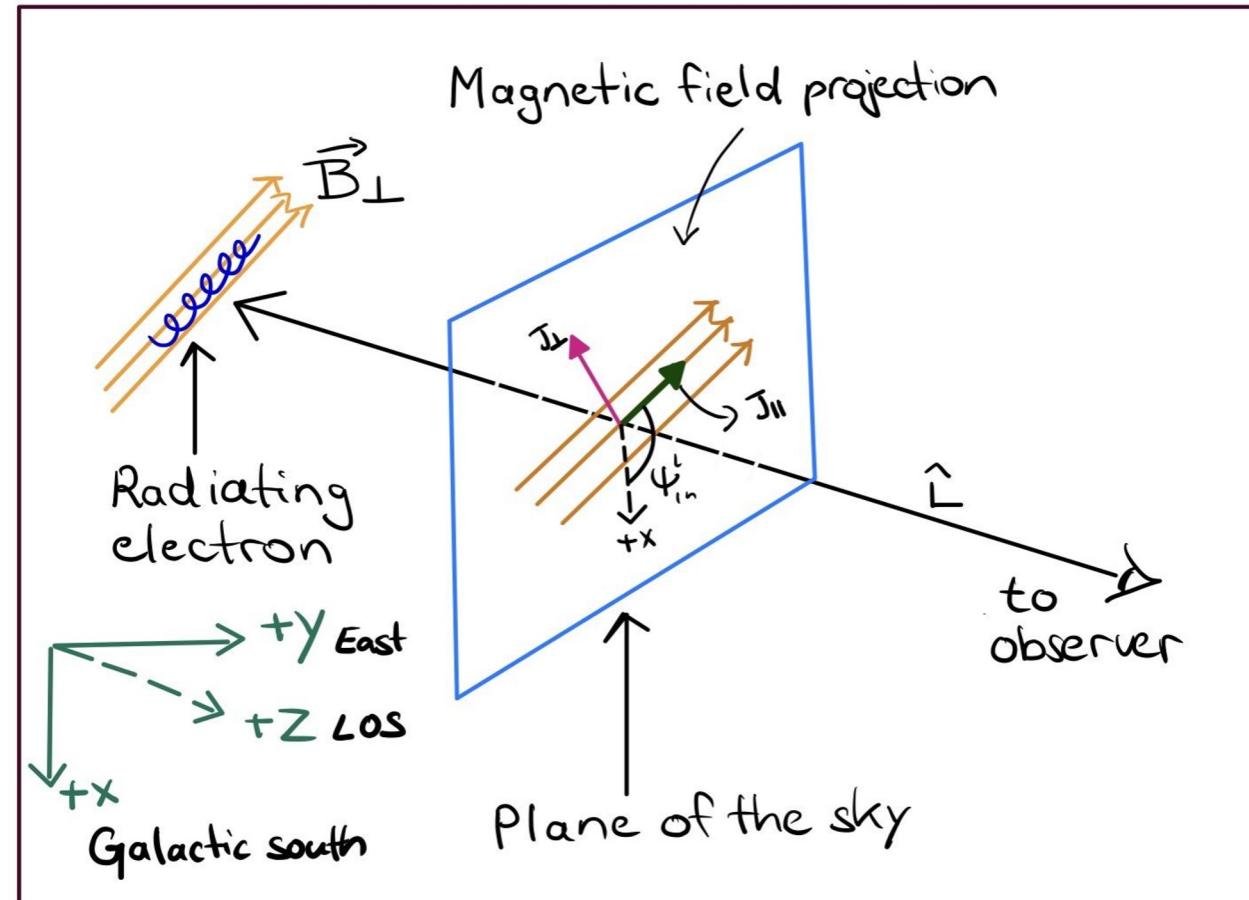

$$\frac{dn_e}{d\log E_e} = C_{\text{norm}} \left(\frac{E_e}{E_{10\text{GeV}}} \right)^{-p+1} e^{-r/R_{\text{el}}} \operatorname{sech}^2 \left(\frac{z}{Z_{\text{el}}} \right)$$

Together magnetic fields and non-thermal electrons give Synchrotron!

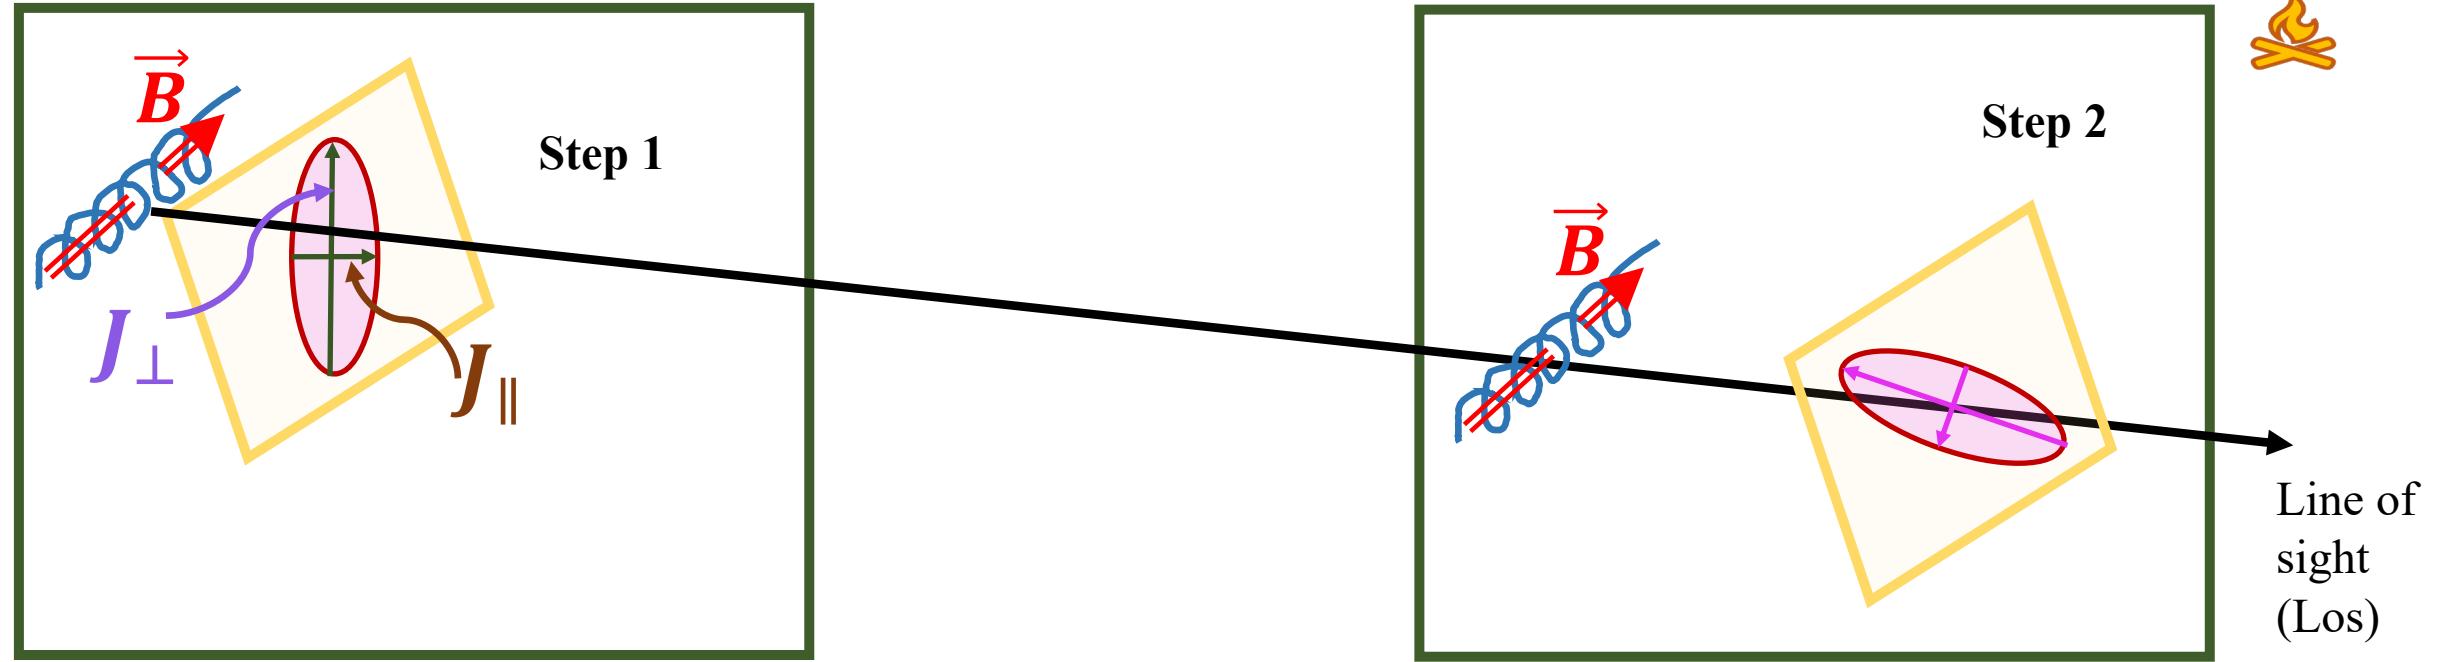

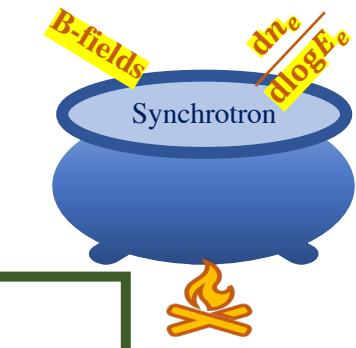

$$R_{\text{el}} \& Z_{\text{el}} = 5 \text{ kpc and } 6 \text{ kpc}$$

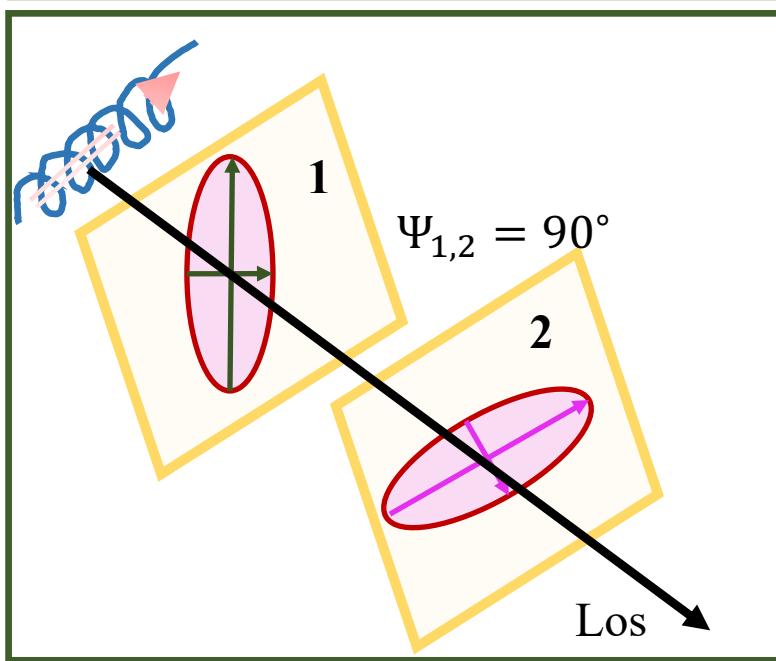

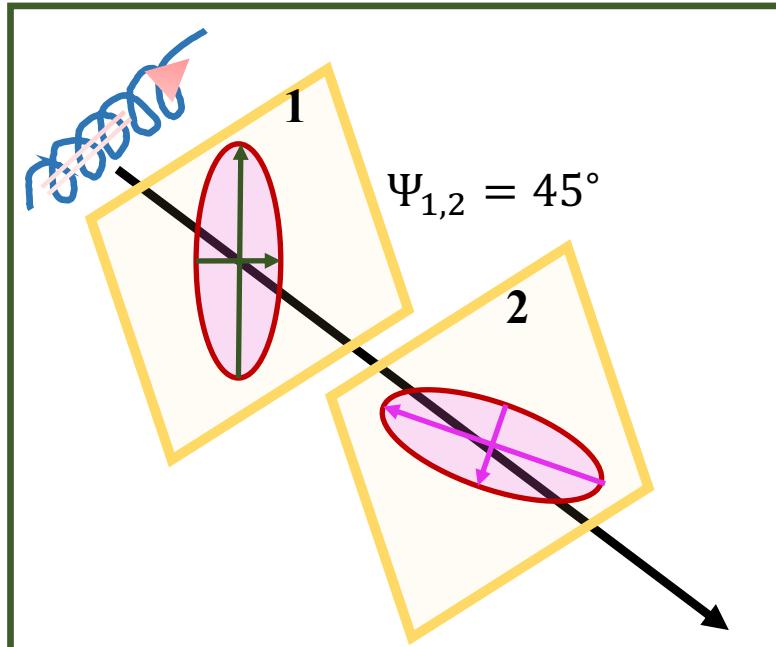

Synchrotron radiation – standard picture

Synchrotron radiation – emission ellipses

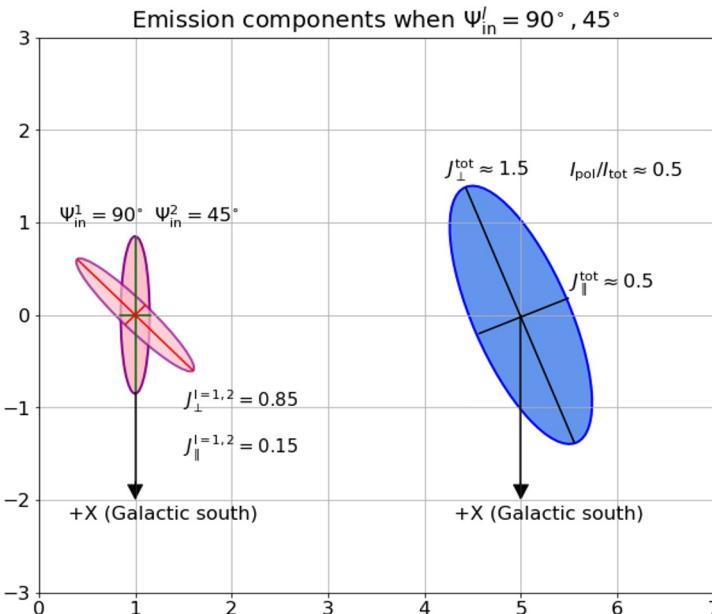

Synchrotron radiation

Polarised synchrotron

Probes magnetic field strength
and geometry

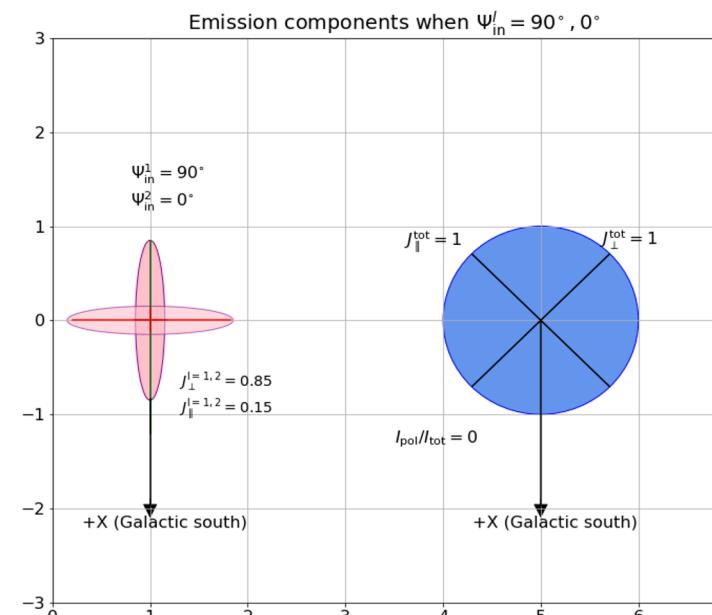

Unpolarised synchrotron

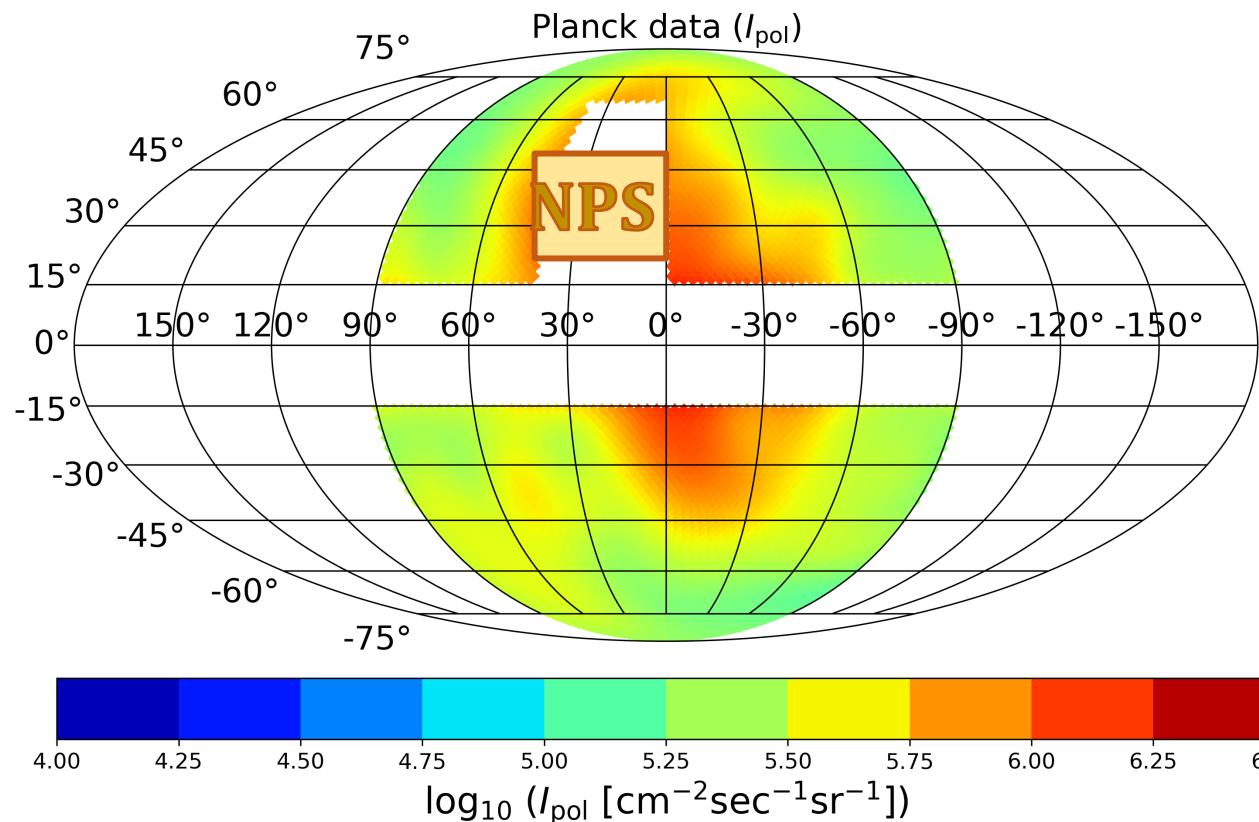

Probes magnetic field strength
only

Maximum emission is
observed when the electron
pitch angles are
perpendicular to magnetic
fields.

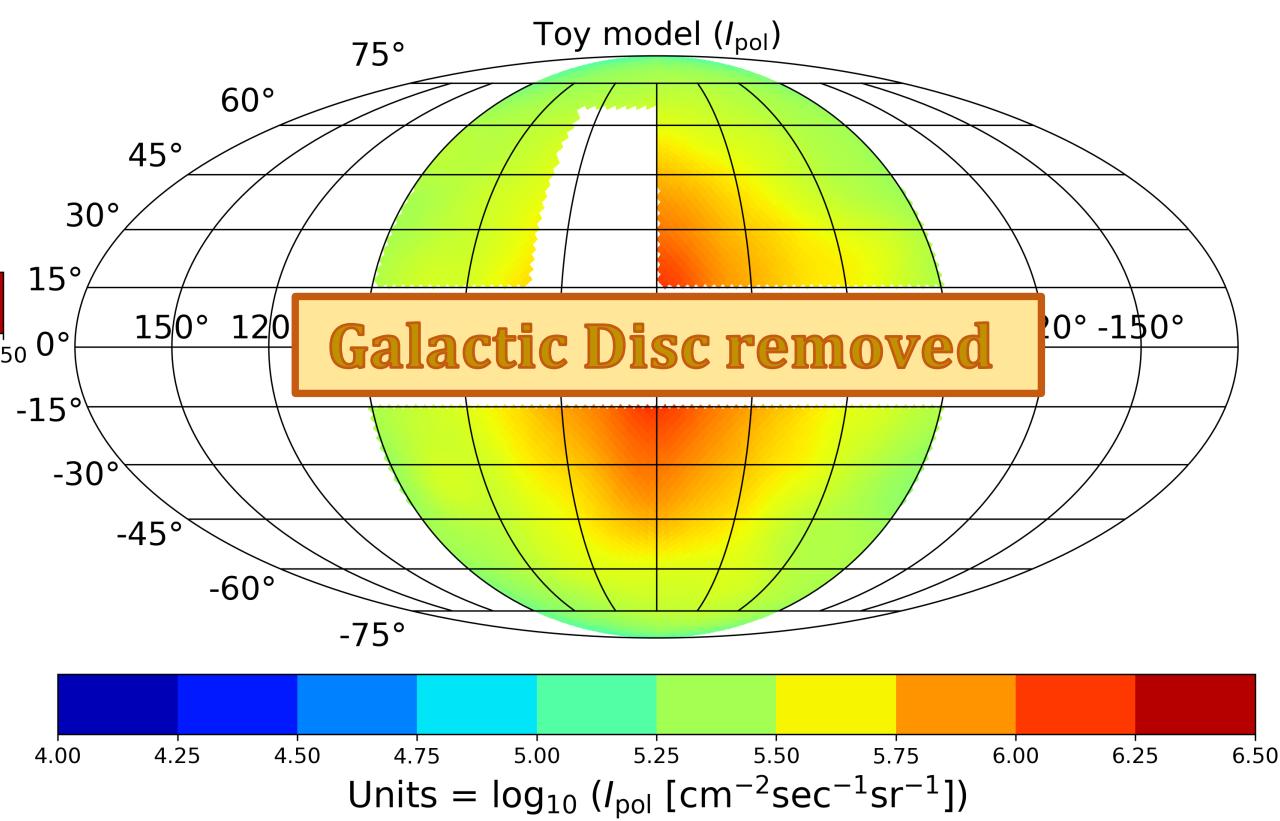

V. Shaw - DESY, Zeuthen, TeVPA 2022

Results – Best fit case

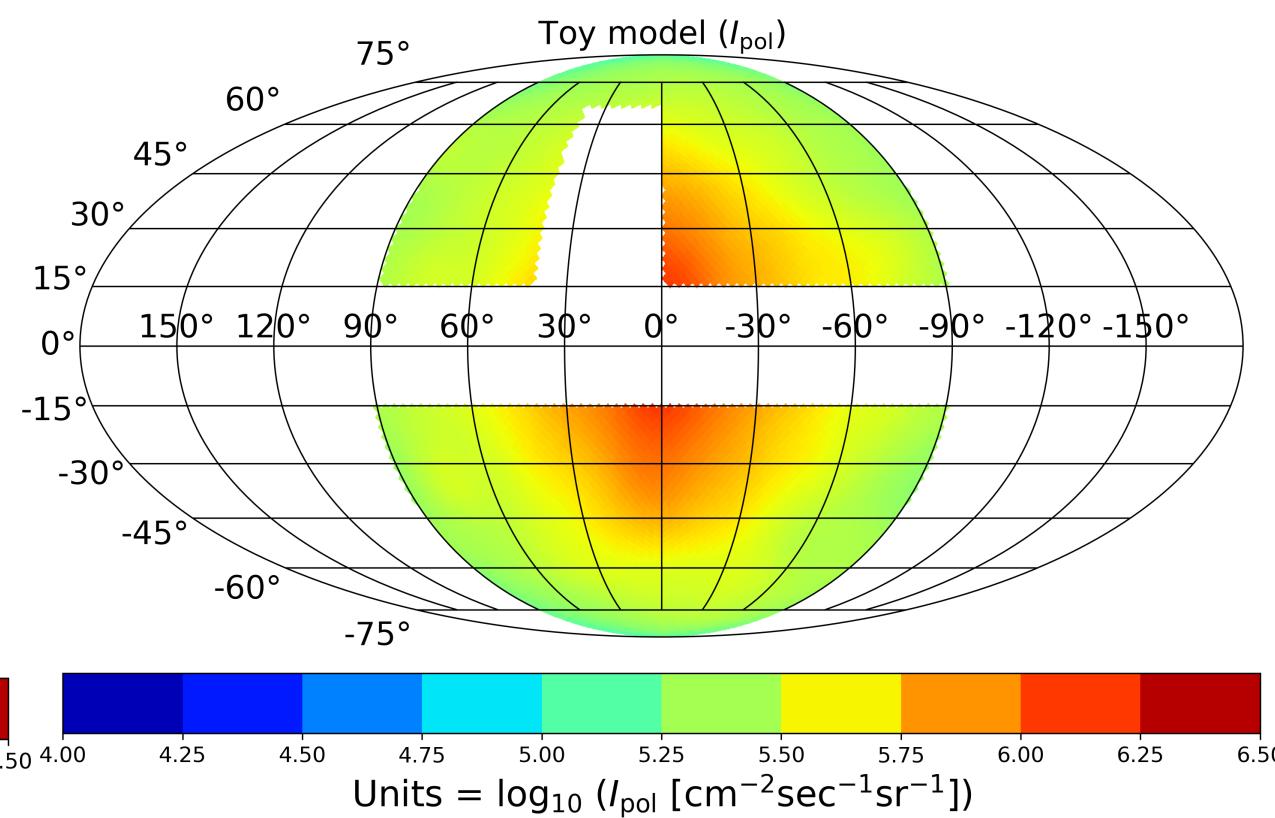

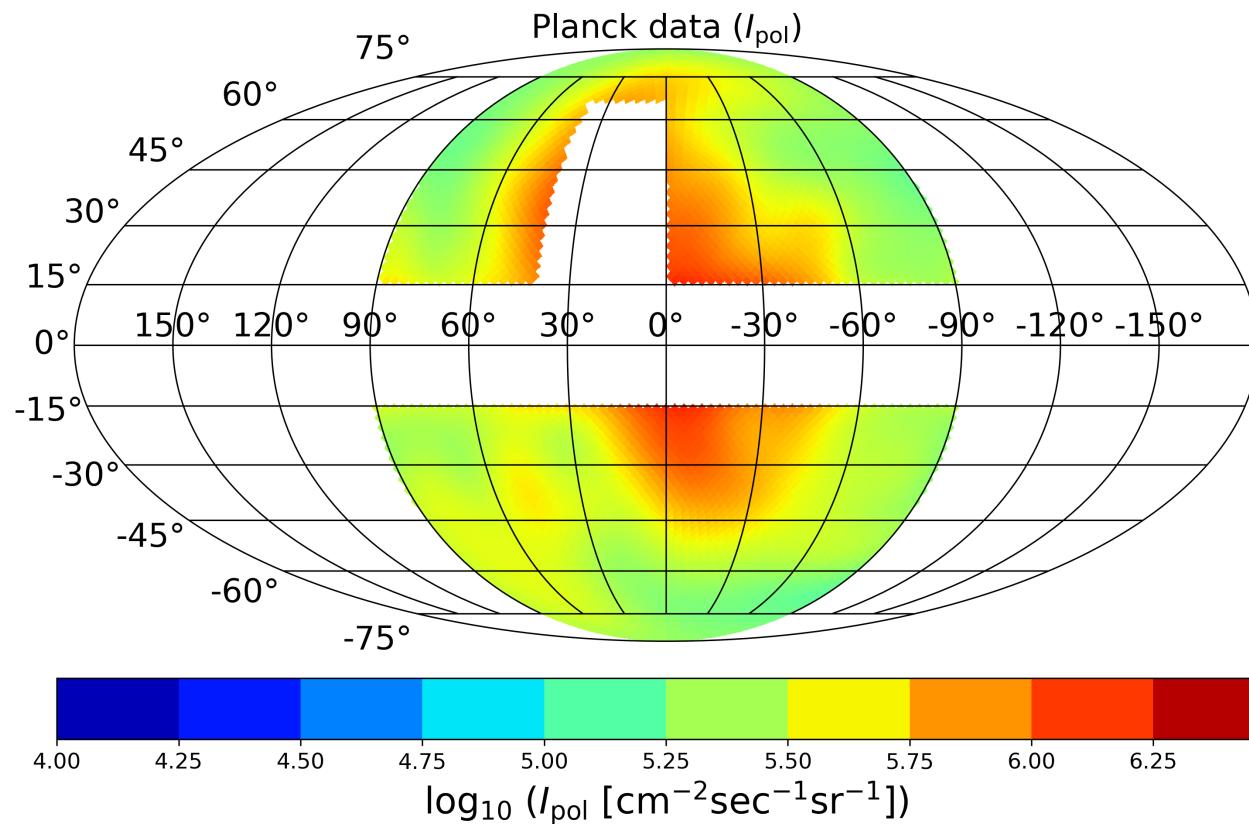

15° Gaussian smoothening

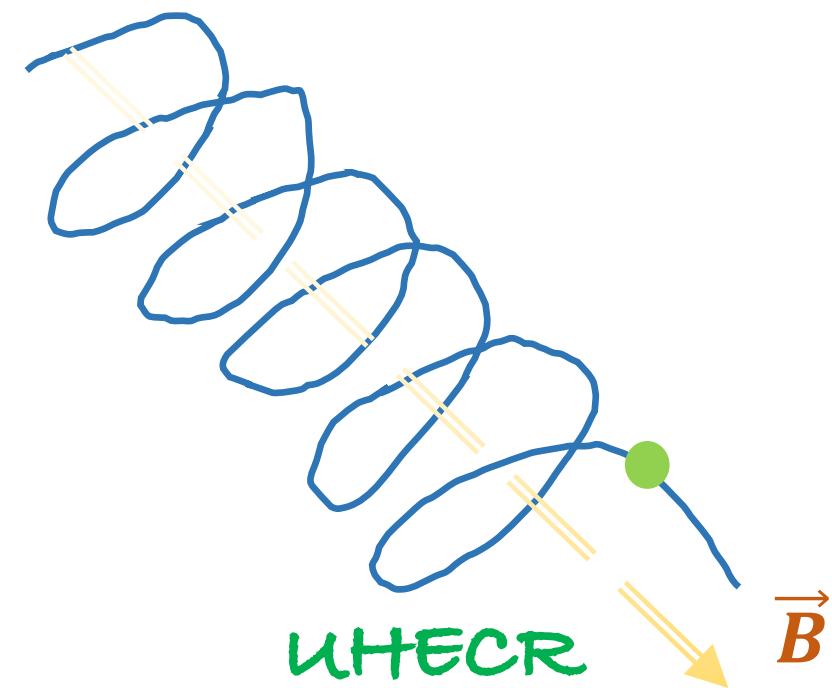

Constraints

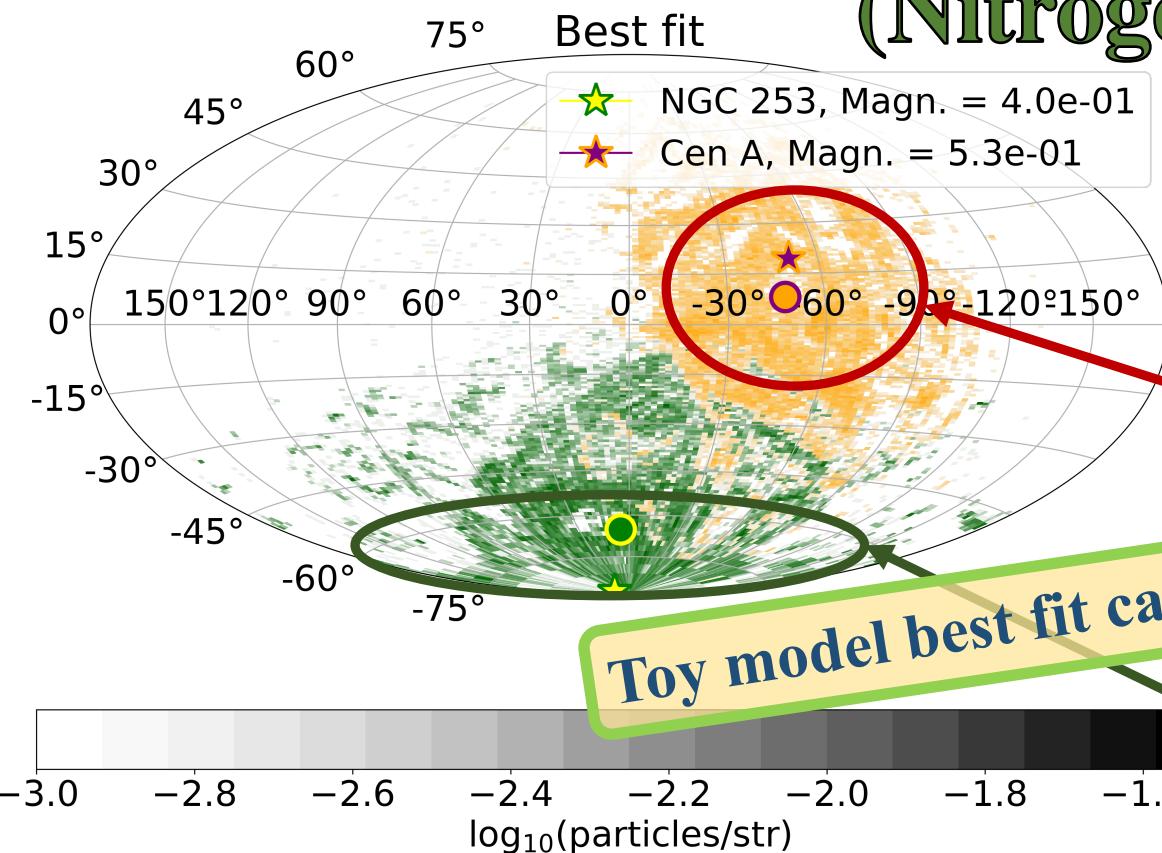

Best-fit value with 1σ constraint		
Parameter	Best-fit value	Description
B_{str}	$3.96^{+6.63}_{-1.96} \mu\text{G}$	Structured field strength
B_{tur}	$6.72^{+9.97}_{-3.56} \mu\text{G}$	Turbulent field strength
$R_{\text{Mag}} = R_{\text{el}}$	5^{+1}_{-0}kpc	Radial cut off
$Z_{\text{Mag}} = Z_{\text{el}}$	6^{+1}_{-0}kpc	Azimuthal cut off
$\log_{10} (C_{\text{norm}} [\text{cm}^{-3}])$	$-11.72^{+0.62}_{-0.93}$	Electron density at 10 GeV

Backtracking of UHECRs through toy model using CRPropa3

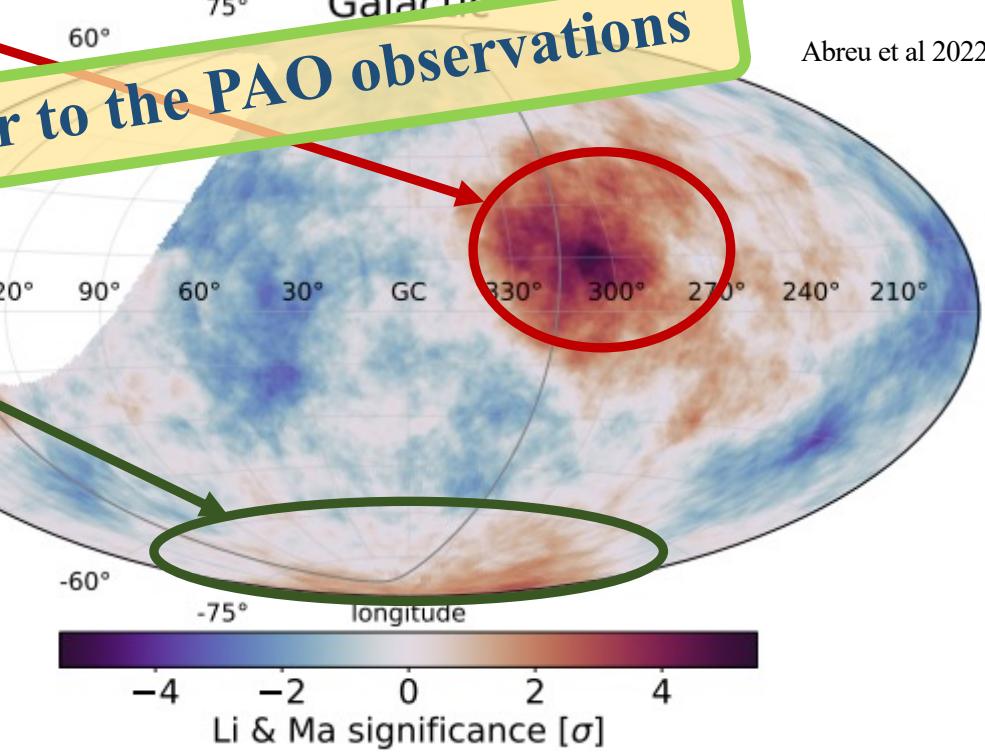

Arrival directions of UHECRs – Toy Model vs Auger (Nitrogen at 40 EeV)

Toy model best fit case is similar to the PAO observations

$\sigma(E_{\text{Auger}} \geq 41 \text{ EeV}) - \Psi = 24^\circ$

Abreu et al 2022

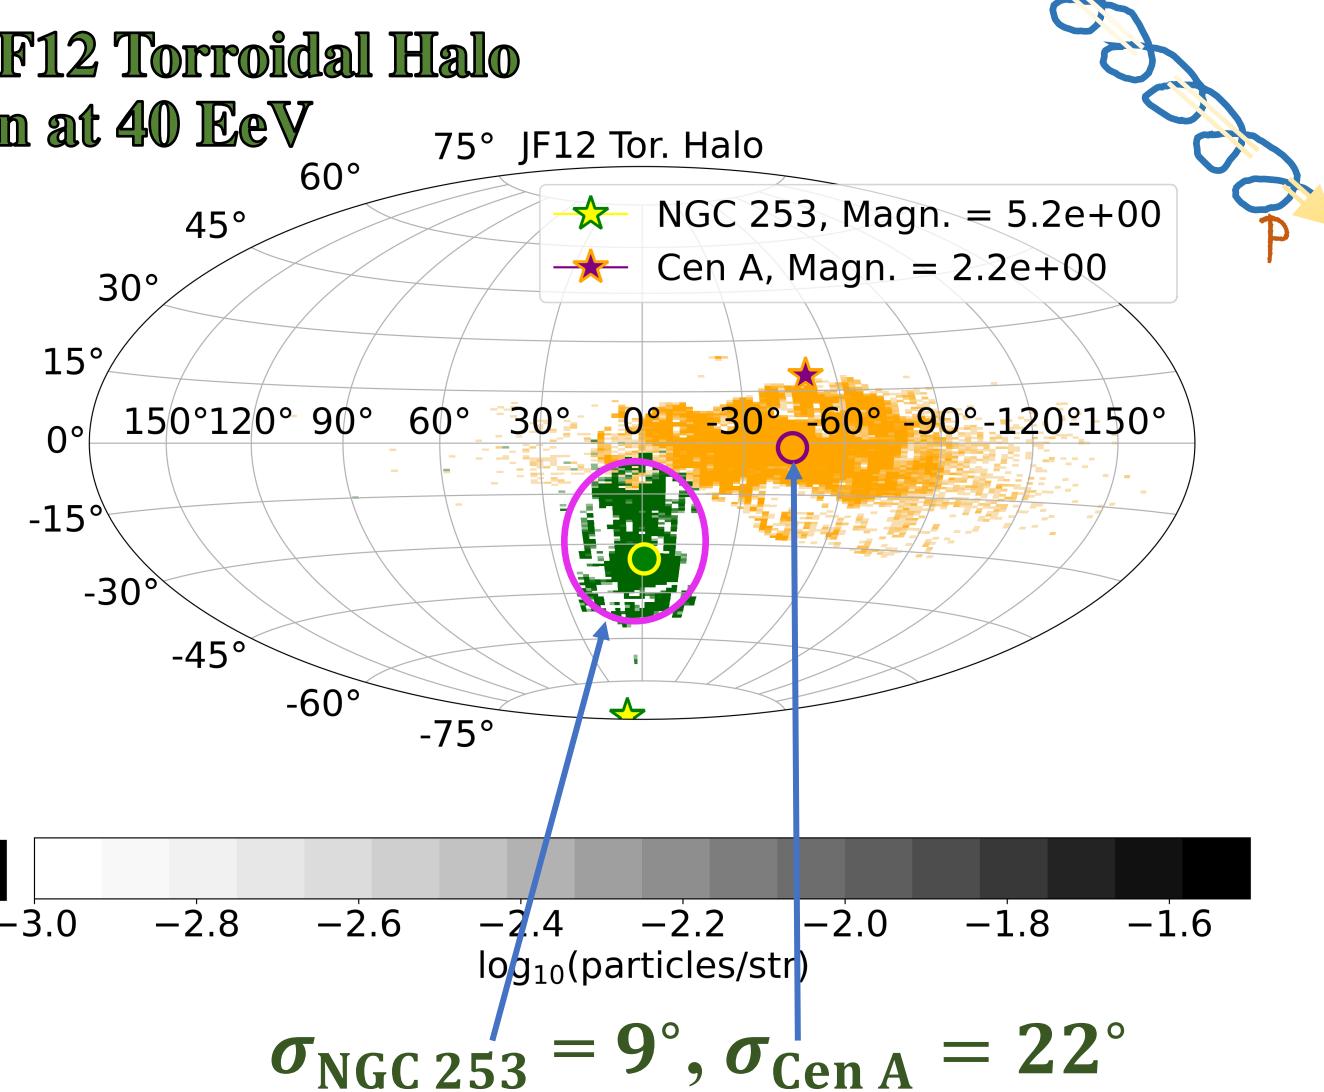

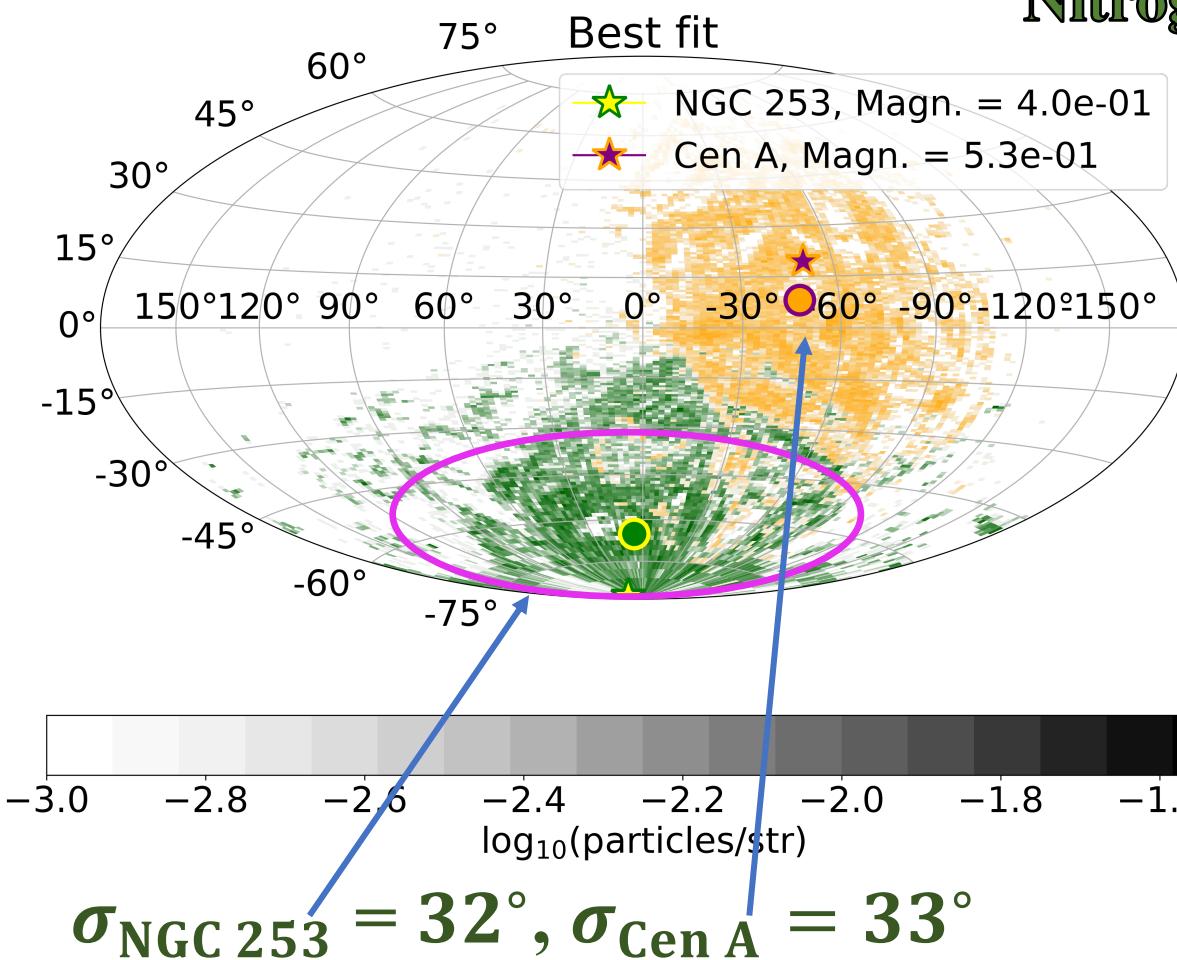

Choice of rigidity & species based on PAO

Aab et al 2014 & 2018

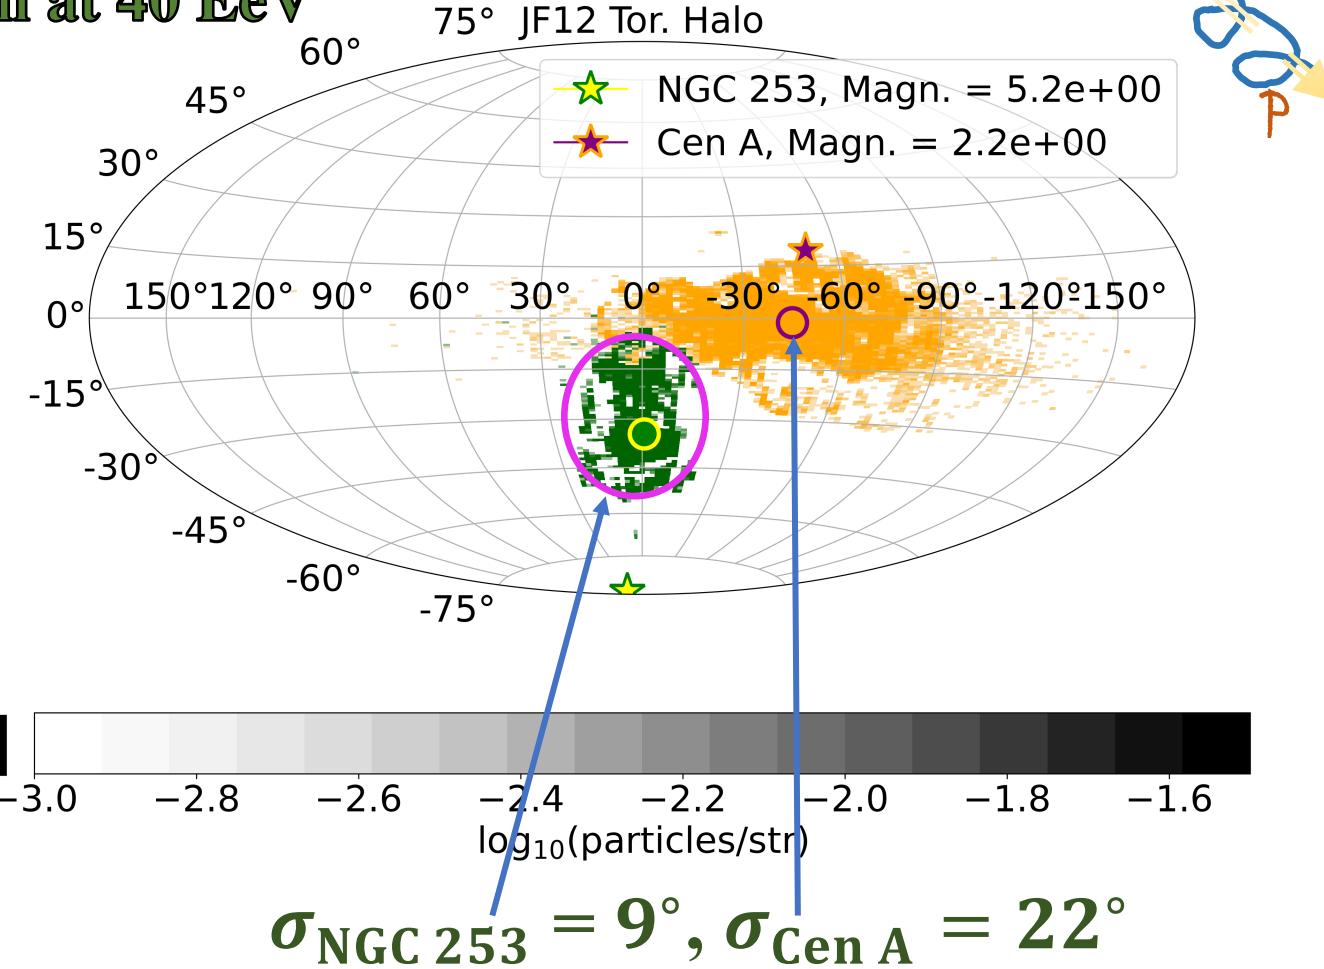

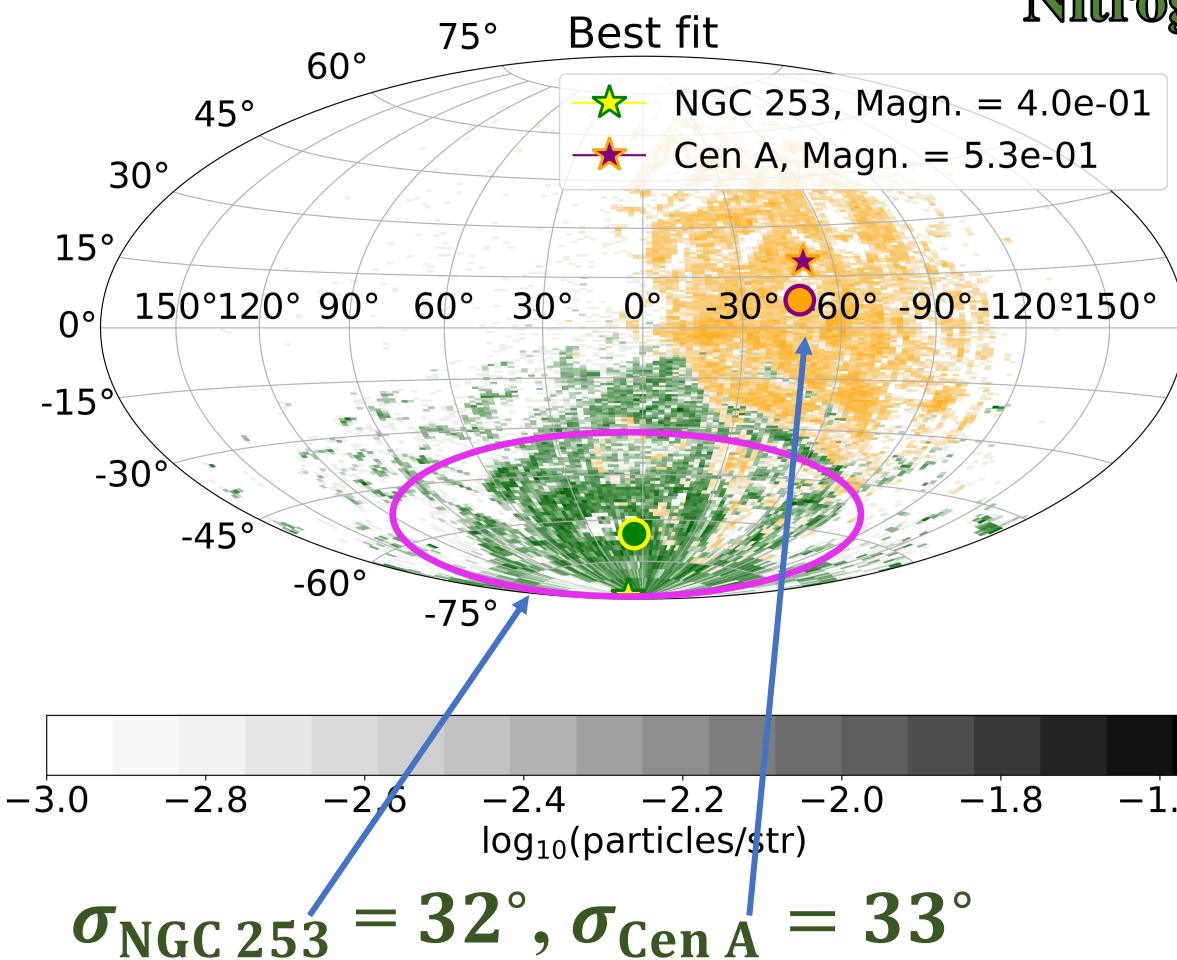

Toy Model vs JF12 Toroidal Halo

Nitrogen at 40 EeV

Toy Model vs JF12 Toroidal Halo

Nitrogen at 40 EeV

Structured fields - Overall coherent deflection
Turbulent fields - Spreading out the directions of the particle deflections around this overall deflected direction

Spreading Effect - Toy model 5-10 times larger than JF12
Deflections are dominated by halo NOT disc

Conclusions & Outlook

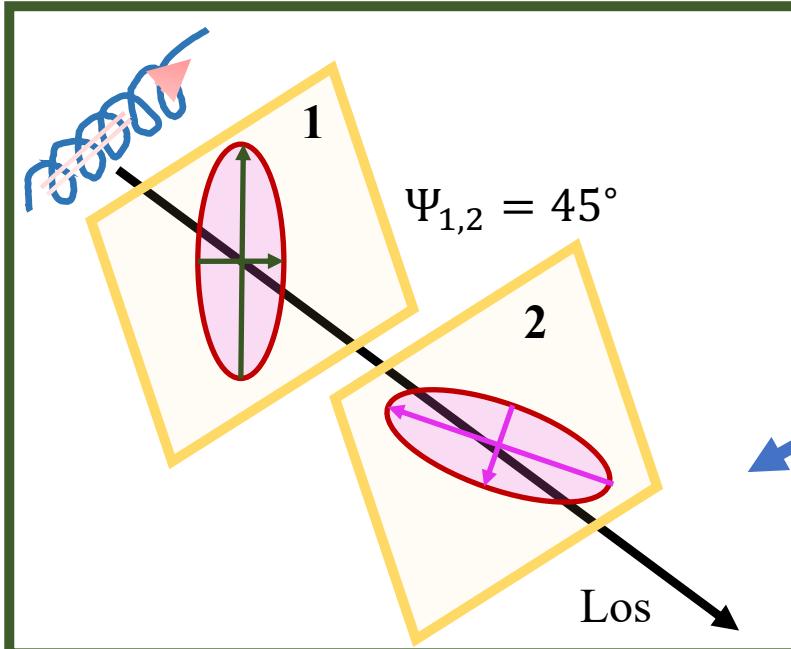

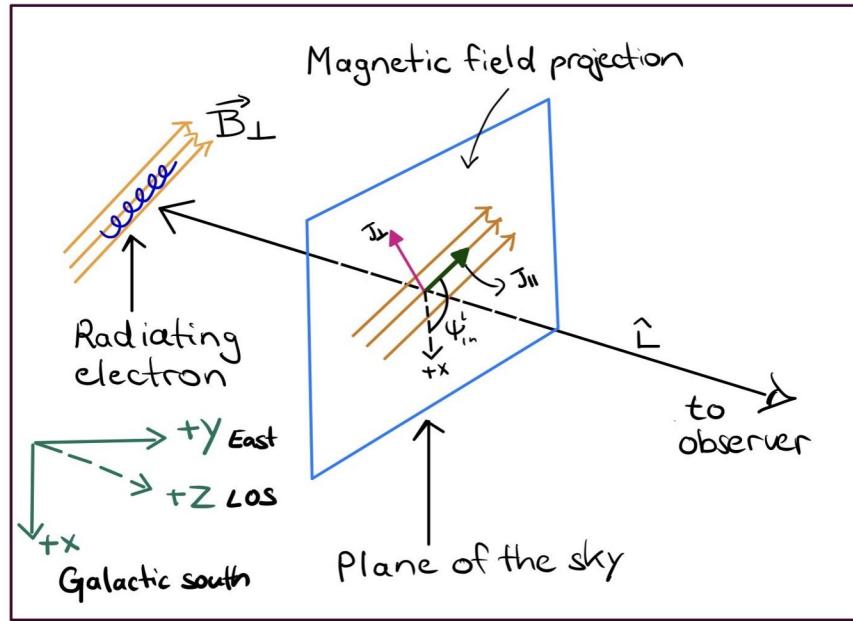

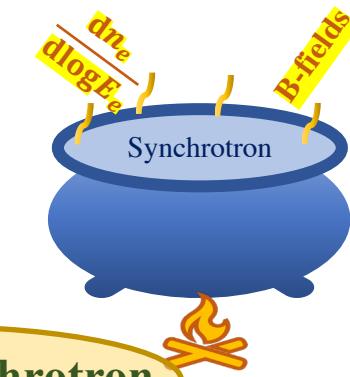

- Our results indicate $\sim 7 \mu\text{G}$ total fields over a large spatial extent with the height of halo being $\sim 6 \text{ kpc}$ in z-direction which is compatible with S-PASS and other observations.
- Arrival direction of cosmic rays is highly tangled with both the structured and turbulent magnetic fields. We find the cosmic ray deflections from our model are similar with NGC 253 and Cen A hotspots from Auger (Abreu et al. 2022).
- Rotation measures from extra-galactic sources like FRBs should be factored in once the MeerKat and FAST data is public.
- C-BASS, Quijote and Lofar data can also be useful for studying the halo at different frequencies in the future.

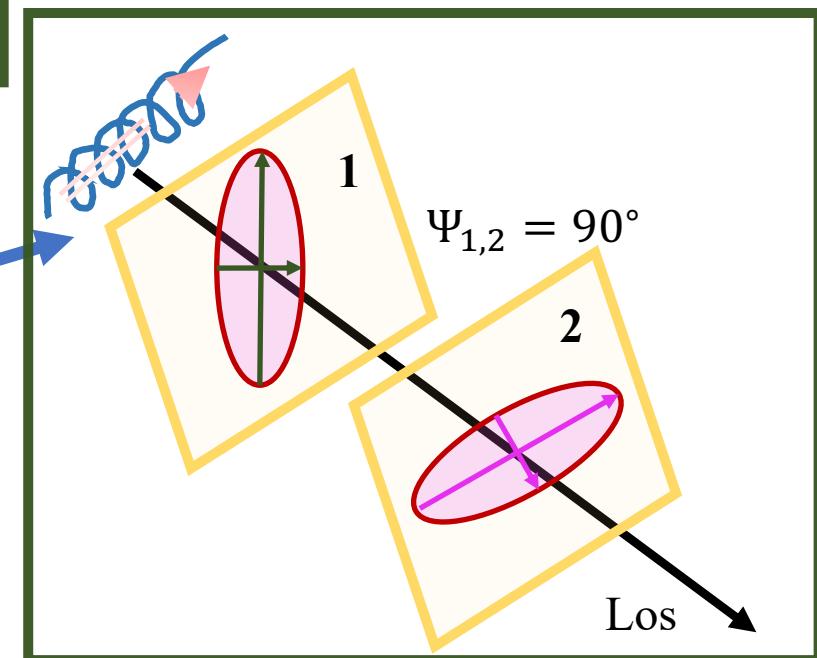

Extras

Synchrotron radiation – emission ellipses

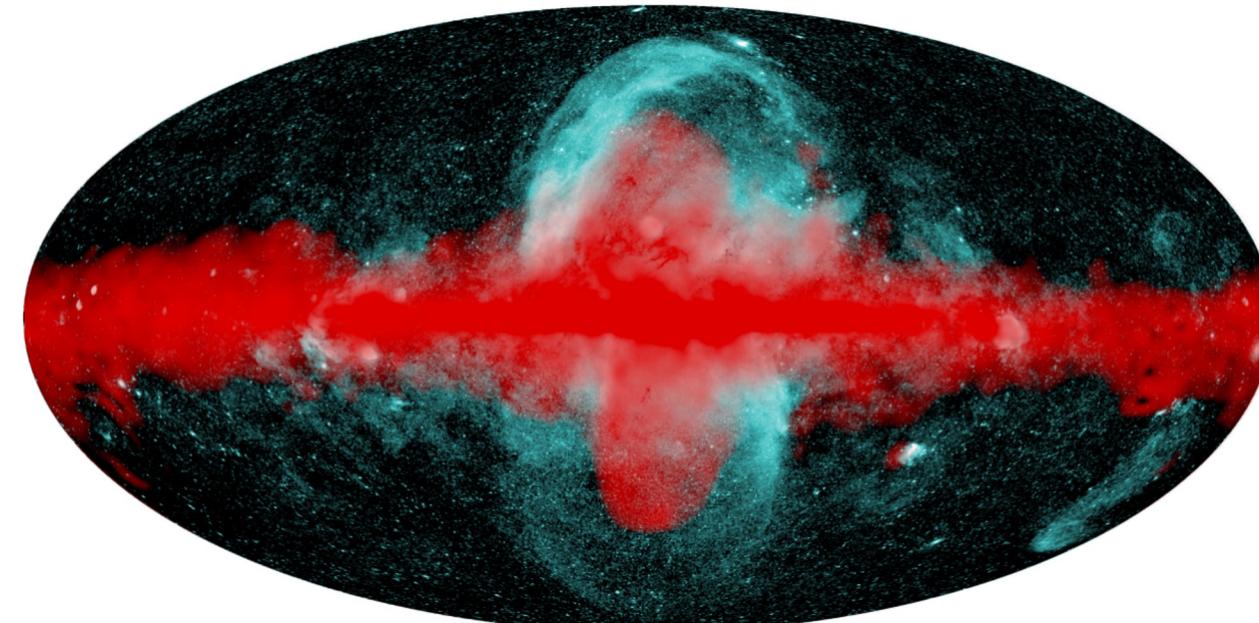

Unpolarised synchrotron

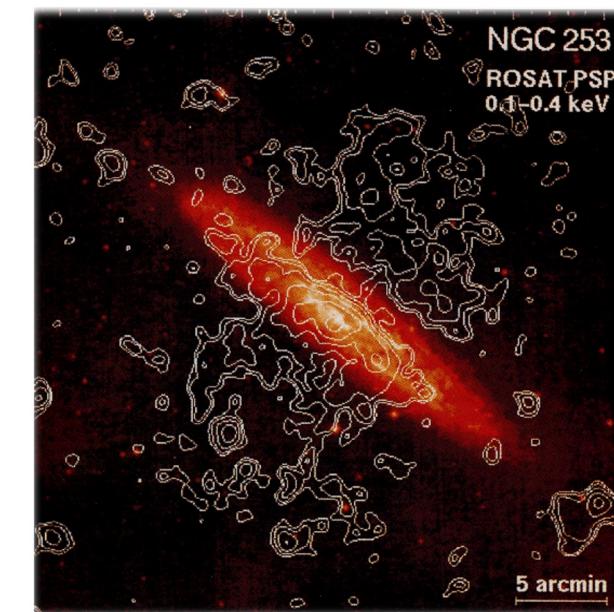

Maximum emission is observed when the electron pitch angles are perpendicular to magnetic fields

Milky way is not a starburst galaxy yet it has outflow!

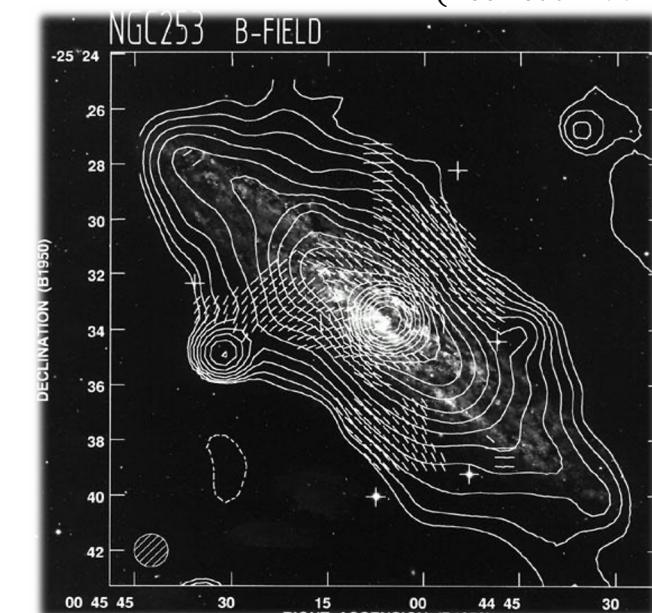

(Pietsch et.al 1996)

Outflows as seen in starburst galaxies!

(Beck et.al 1994)

Total radio intensity (*contours*) and magnetic field orientation of [NGC 253](#).

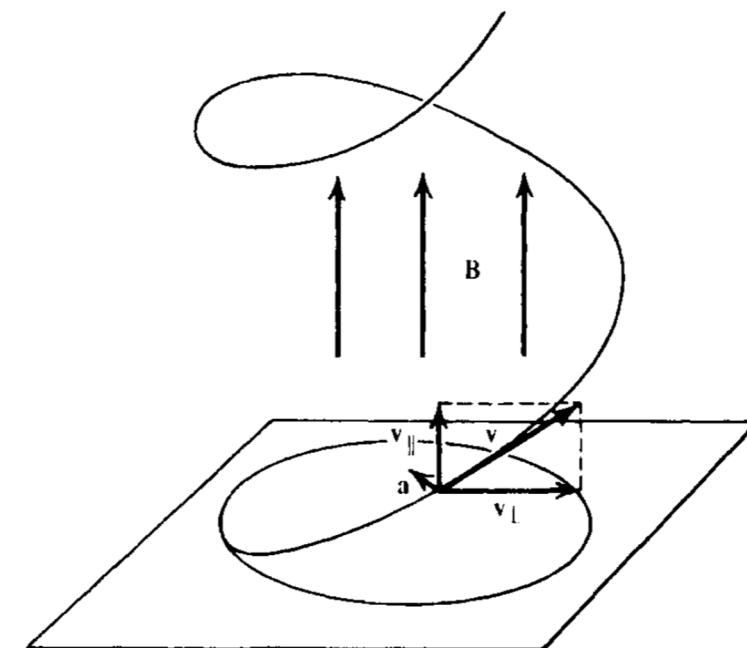

Large scale structures imply large scale magnetic fields

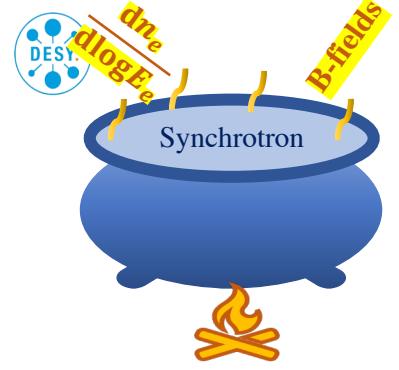

SYNCHROTRON RADIATION

- "Magneto-bremsstrahlung" = Radiation emitted by relativistic charged particles (mostly electrons) due to acceleration ("gyro-motion") in a static magnetic field.

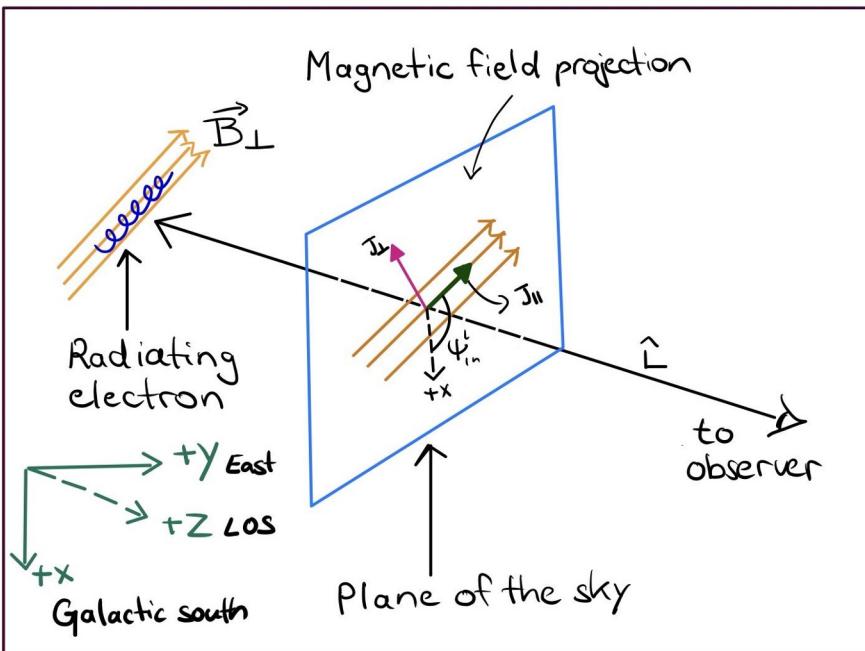

$$\langle P_{syn} \rangle = \frac{4}{3} c \sigma_T \beta^2 \gamma^2 u_B \propto \gamma^2 B^2$$

- u_B : magnetic energy density $\left(\frac{B^2}{8\pi}\right)$
- $\beta\gamma$: speed of electron
- σ_T : Thompson scattering

Polarised synchrotron radiation

$$J_{\perp}^l = \frac{1}{\tau} \int_{\log E_e^{\min}}^{\log E_e^{\max}} \frac{dn_e}{d\log E_e} d\log E_e \left[F\left(\frac{E_{\gamma}}{E_{\gamma}^{\text{peak}}}\right) + G\left(\frac{E_{\gamma}}{E_{\gamma}^{\text{peak}}}\right) \right] \quad (3)$$

and

$$J_{\parallel}^l = \frac{1}{\tau} \int_{\log E_e^{\min}}^{\log E_e^{\max}} \frac{dn_e}{d\log E_e} d\log E_e \left[F\left(\frac{E_{\gamma}}{E_{\gamma}^{\text{peak}}}\right) - G\left(\frac{E_{\gamma}}{E_{\gamma}^{\text{peak}}}\right) \right] \quad (4)$$

where

$$\tau^{-1} = \frac{\sqrt{3}\alpha}{4\pi} \frac{B_{\perp}}{B_{\text{crit}}} \frac{m_e c^2}{\hbar}, \quad E_{\gamma}^{\text{peak}} = \frac{3}{2} \Gamma_e^2 \frac{B_{\perp}}{B_{\text{crit}}} m_e c^2,$$

and

$$F(x) = x \int_x^{\infty} K_{5/3}(x') dx', \quad G(x) = x K_{2/3}.$$
