

A silicon based polarimeter for pEDM searches

James Gooding

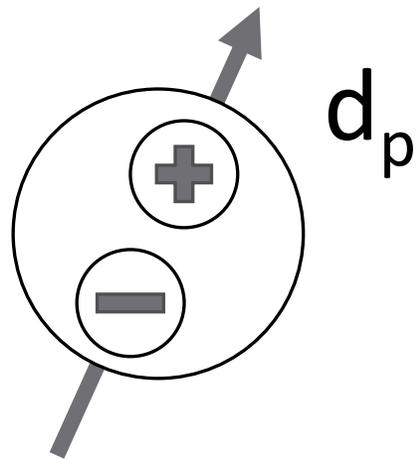

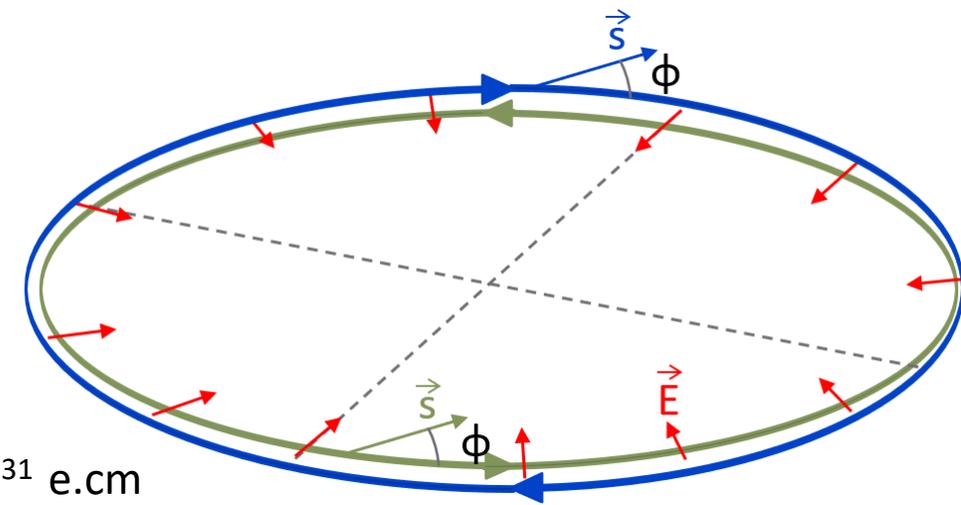

E. Vilella-Figueras, G. Casse, N. Rompotis
T. Bowcock, J. Vossebeld, J. Price

Proton EDM

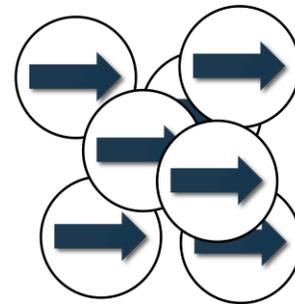

- Overview and experimental method

- Matter/antimatter asymmetry \rightarrow CP violation \rightarrow permanent EDM
- An EDM is caused by separation of permanent charges inside a particle
- Closely connected to spin of the particle which is influenced by E & B fields
- The standard model predicts proton (and neutron) EDM's at the level of 10^{-31} e.cm
- Some BSM predict nucleon EDM's in the range 10^{-24} - 10^{-28} e.cm range
- Neutron EDM limit: d_n is $(0.0 \pm 1.1) \times 10^{-26}$ e.cm

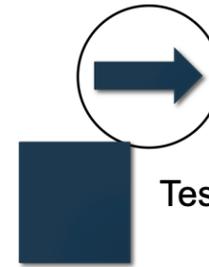

Sensitivity target

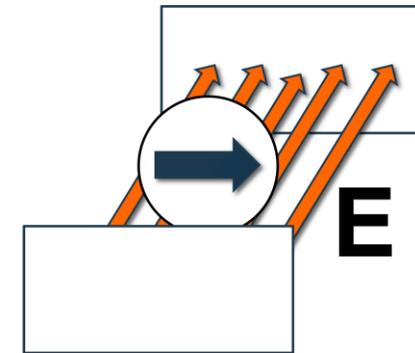

$\sim 10^{-29}$ e.cm

Polarize Beam

Test Polarization

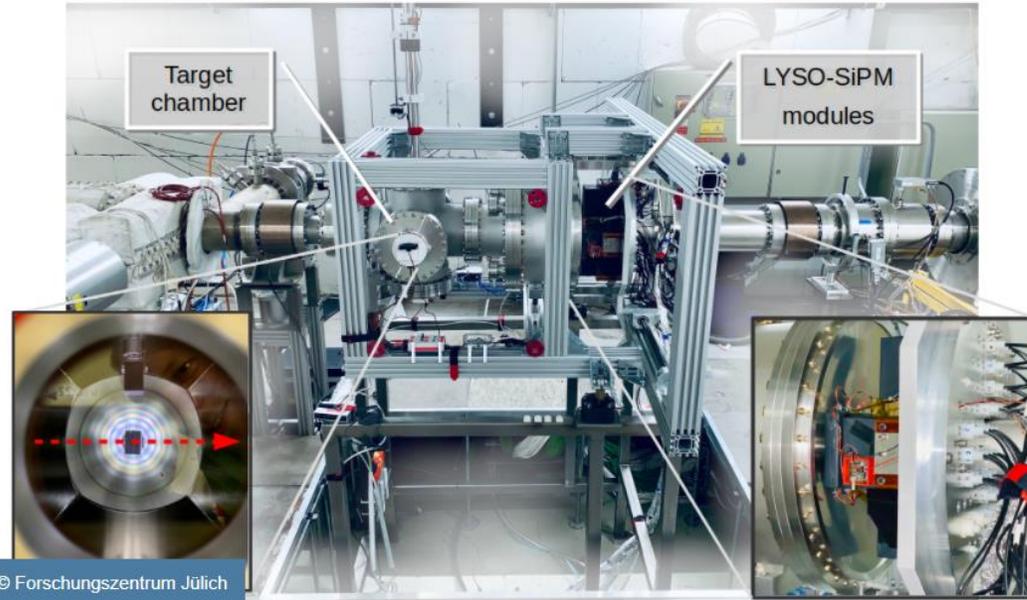

Continuous E field
Interaction over ~ 1000 s

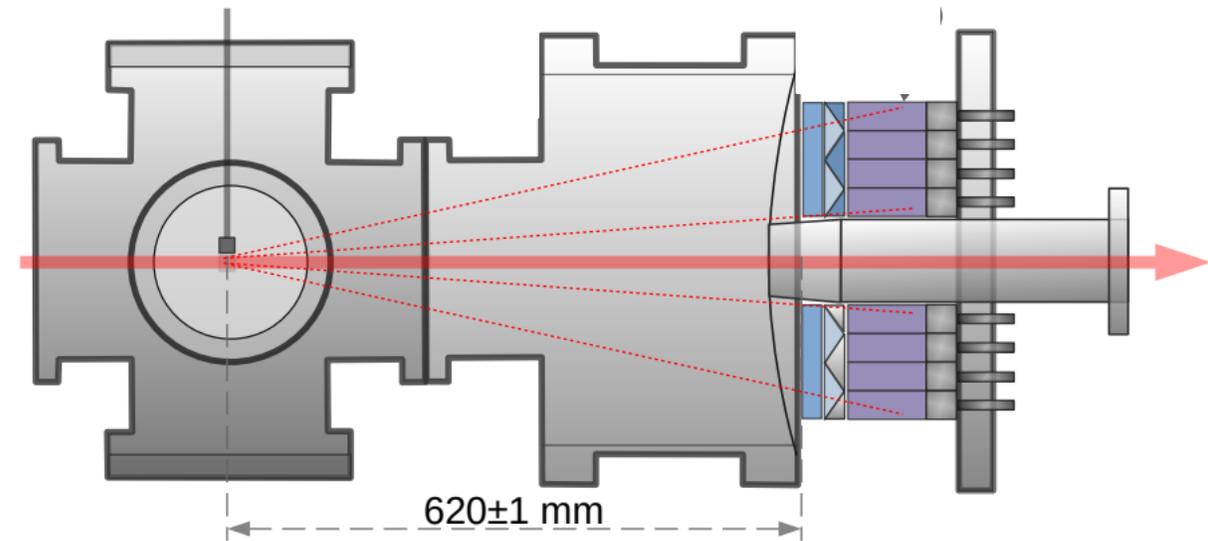

Continuous
Polarization
Measurement

Current Polarimeter

- JePo (JEDI Polarimeter)

- Protons are sampled from the beam and scattered from a carbon target
- Elastic scattering direction is affected by beam polarization
- LYSO calorimeters are used to determine elastic hits
- Plastic scintillator grid measures positions and thus asymmetry
- Level of L/R asymmetry observed indicates beam polarization

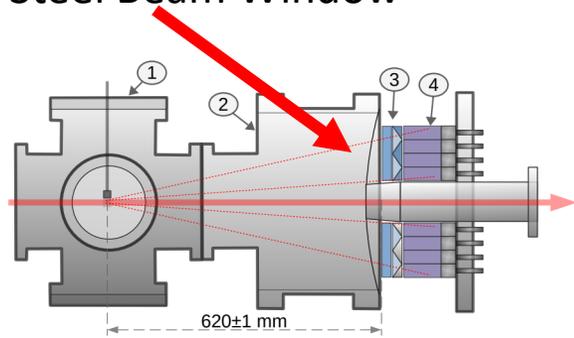

doi.org/10.1088/1748-0221/15/12/p12005

www.jara.org/en/research/fame/news/detail/JEDI-Polarimeter-installed

Current Polarimeter

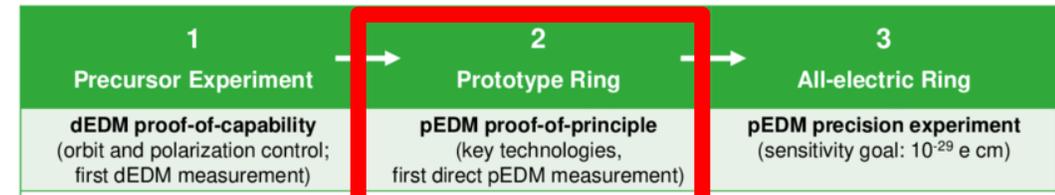

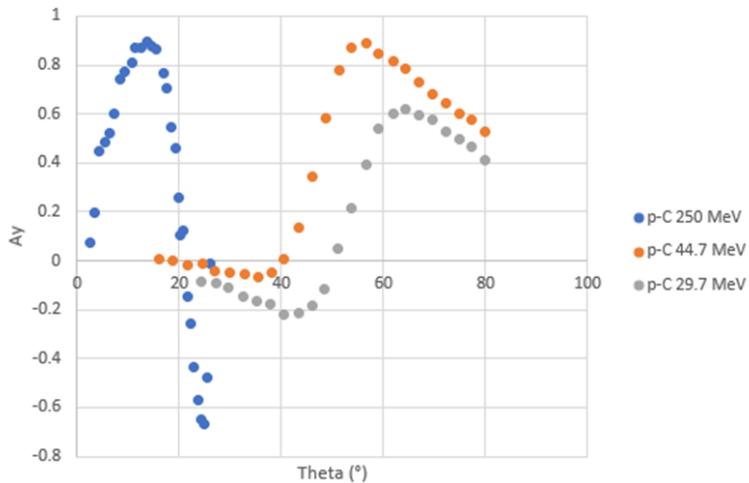

- JePo low energy incompatibility

800 μ m Steel Beam Window

JePo Angular acceptance 4 – 15 degrees

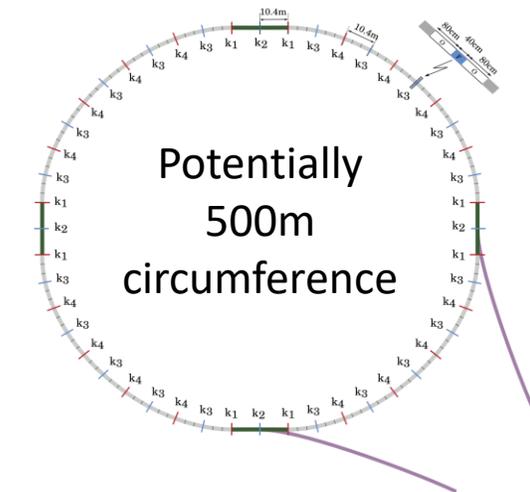

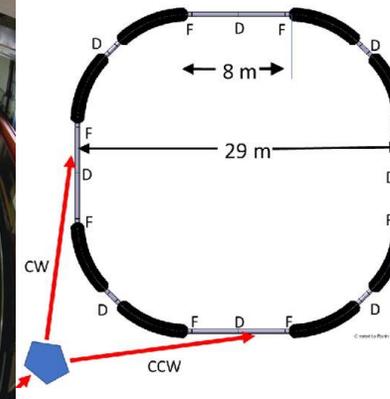

p-C asymmetry dependence on proton energy

270 MeV

30-45 MeV

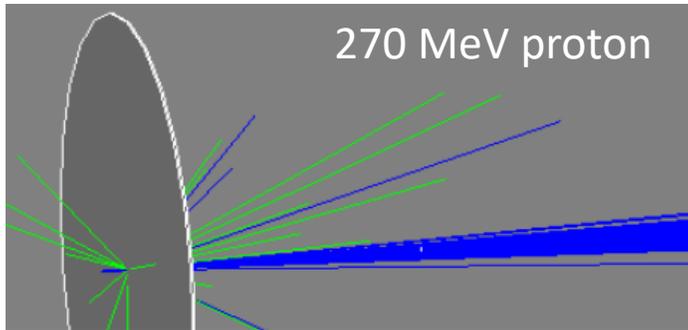

270 MeV

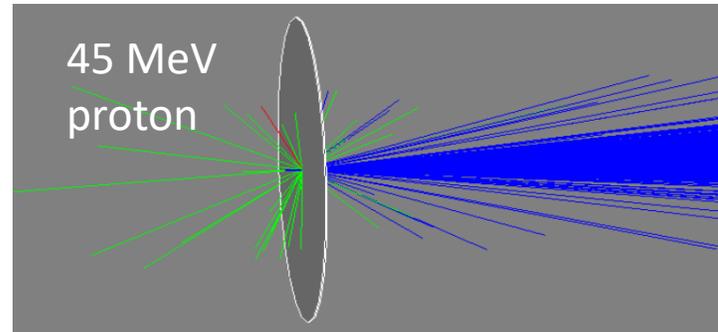

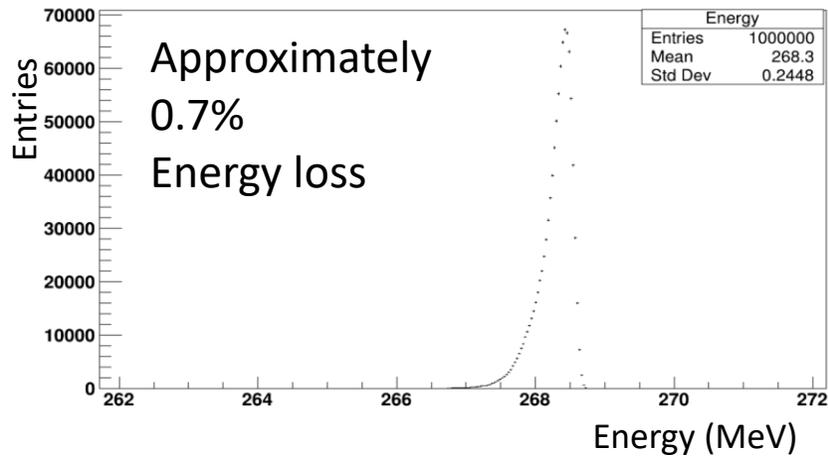

Current Polarimeter

- The necessity of low material budget

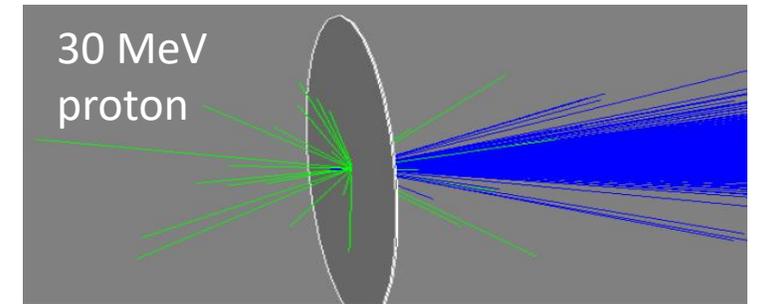

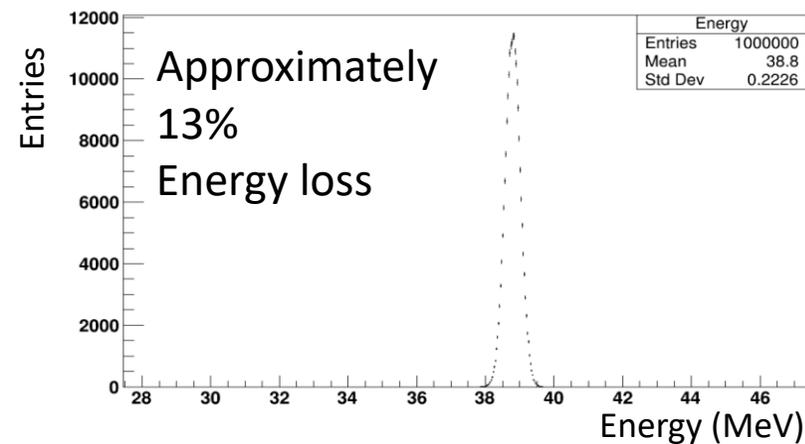

- Strong effect from the current 800 um beam window at lower energies
- **Another approach will be needed for low energy**
- In vacuum, low material polarimeter is desirable

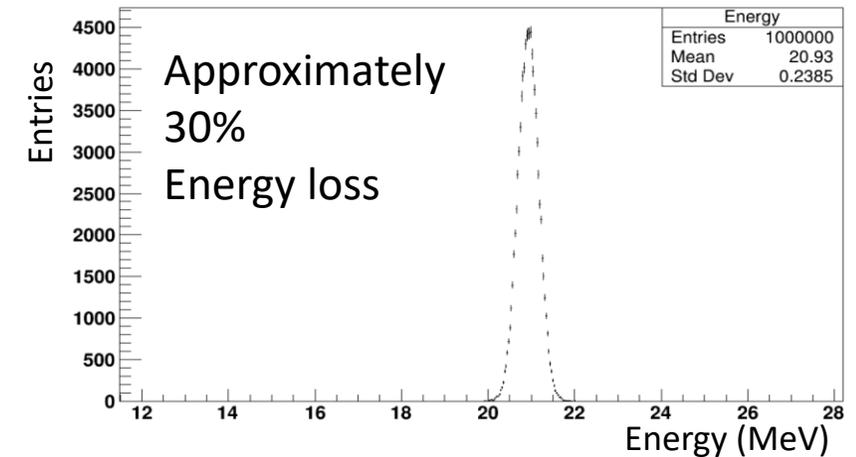

Energy

Energy

Energy

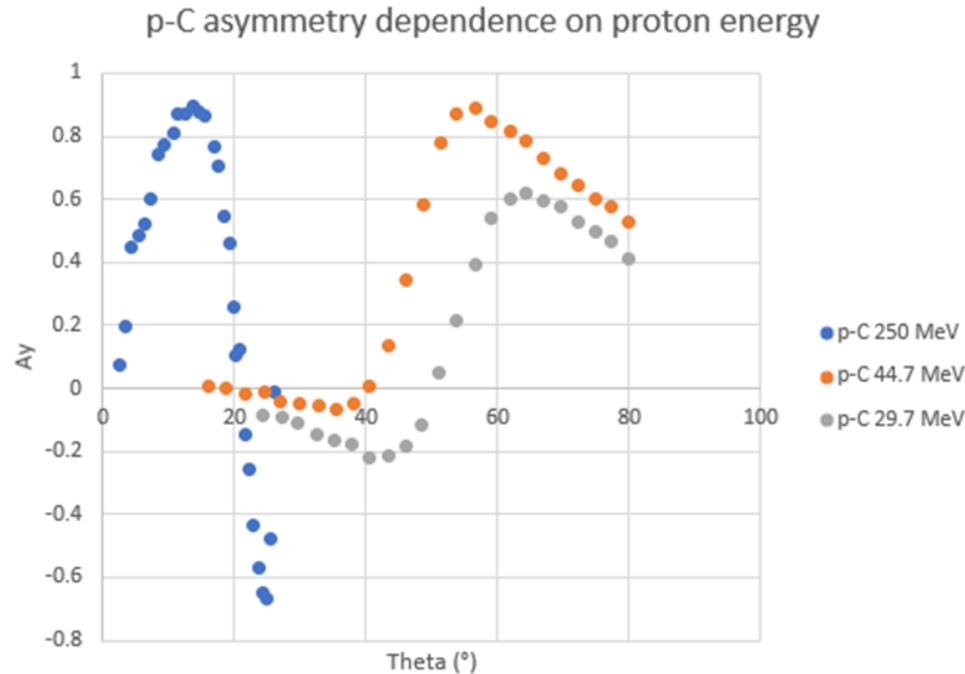

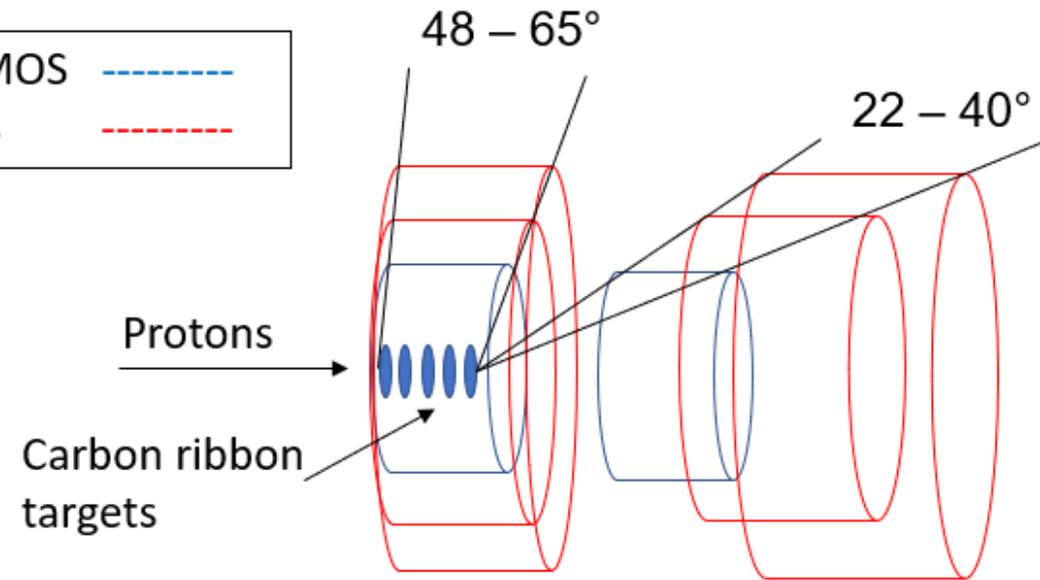

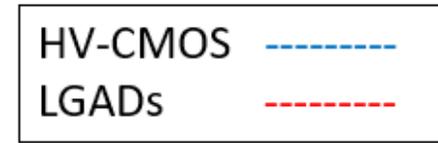

Proposal for a silicon time of flight polarimeter

Not to scale

- Concept and angular acceptance

- HV-CMOS position layer
- LGADs in a time of flight configuration for energy measurement

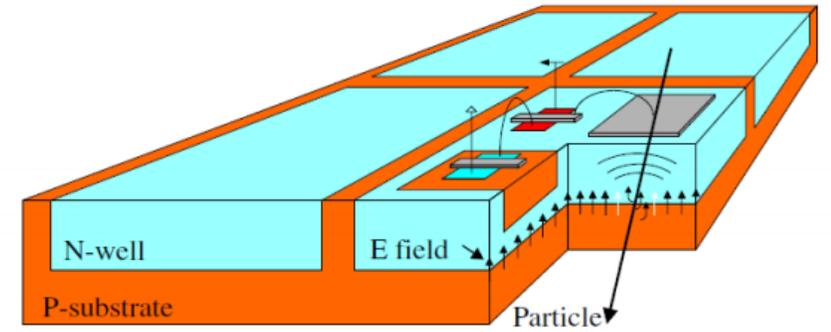

- A_y is the analysing power (the amount of asymmetry that should be observed for a given polarisation at a given angle)
- Thin detectors can be used with minimal angular resolution loss
- $4^\circ - 15^\circ$ (Current JePo) \rightarrow $\sim 40^\circ - 60^\circ$ (Low energy polarimeter)
- Surrounding the detector at a lower rate requires larger detection area.

HVCMOS – High Voltage CMOS

- Overview

- CMOS structure inserted in an isolated deep N-Well
- High resistivity wafers in a standard commercial process allow large depletion to be easily achieved at a low cost compared to other detector systems such as hybrid silicon
- Different available options with active development programme in Liverpool

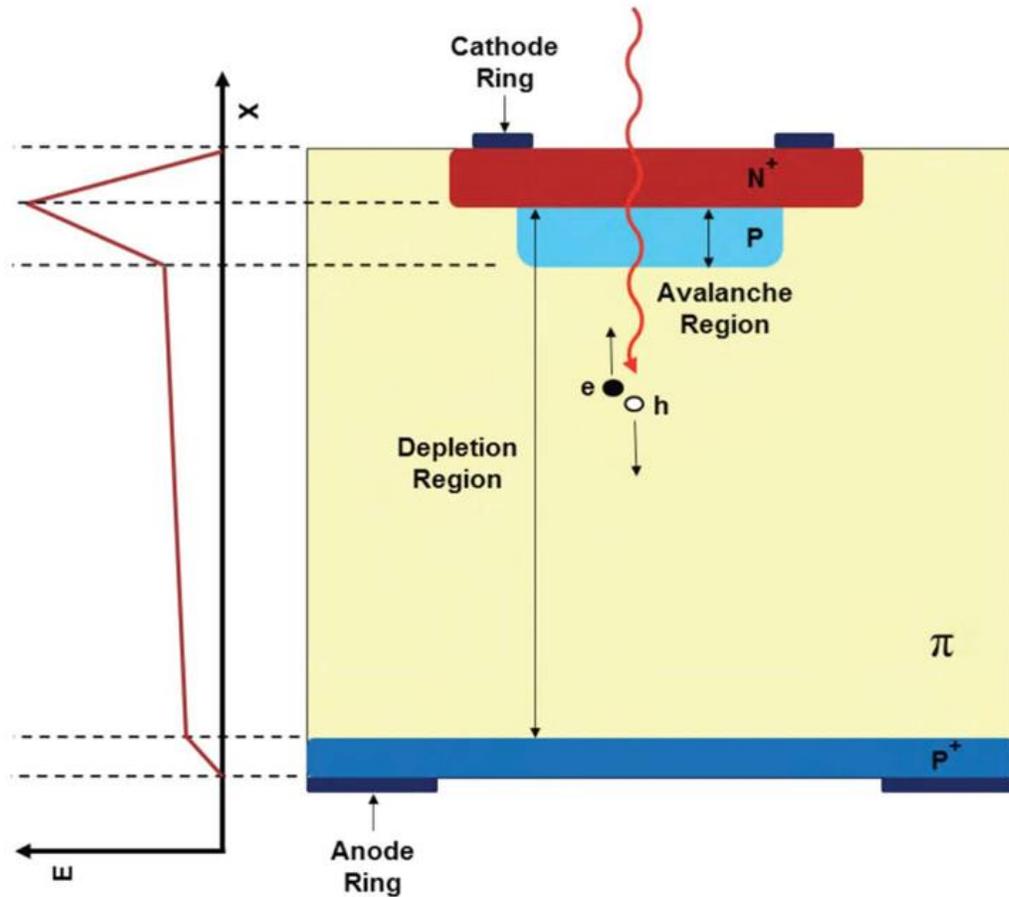

- I. Peric et al (2007)

- Small pixel sizes ($50\mu\text{m}\times 50\mu\text{m}$)
- Thin modules ($>50\mu\text{m}$)
- High radiation tolerance ($E15\text{ n}_{\text{eq}}/\text{cm}^2$)
- Time resolution (5ns)
- Power consumption ($150\text{ mW}/\text{cm}^2$)

LGAD – Low Gain Avalanche Diodes

- Overview

Standard n^+ implant is typical for silicon diode detectors.

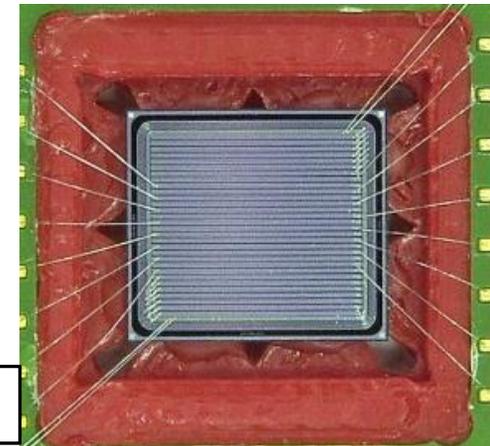

Heavily doped “P” avalanche/gain region producing typical gains of 10-100.

Excellent time resolution in the order of tens of ps.

Sensors can be thinned < 300 μm

http://scipp.ucsc.edu/~schumm/talks/atlas/LGAD/SCHUMM_CPAD-2018.pptx

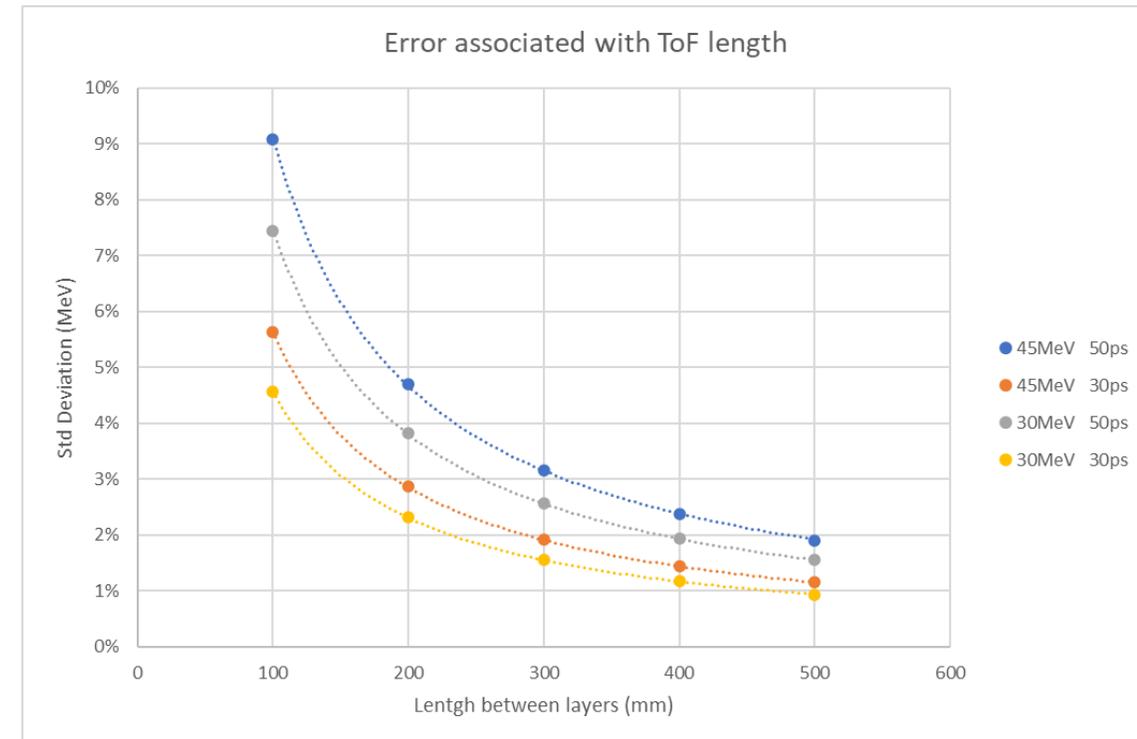

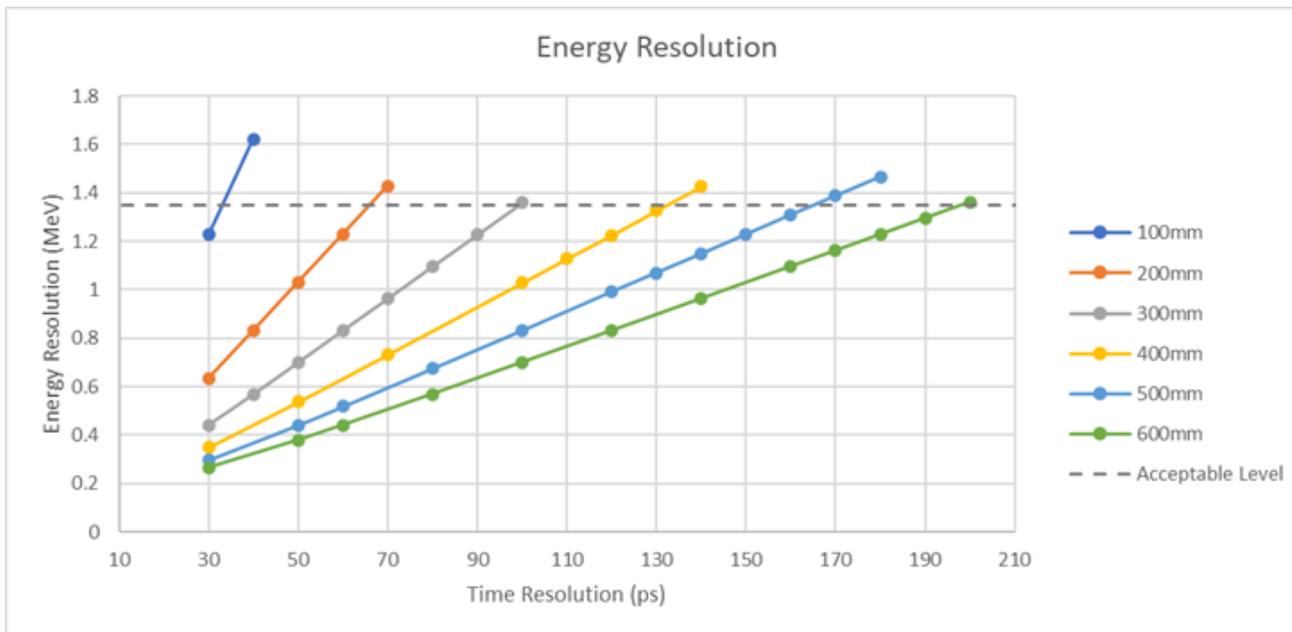

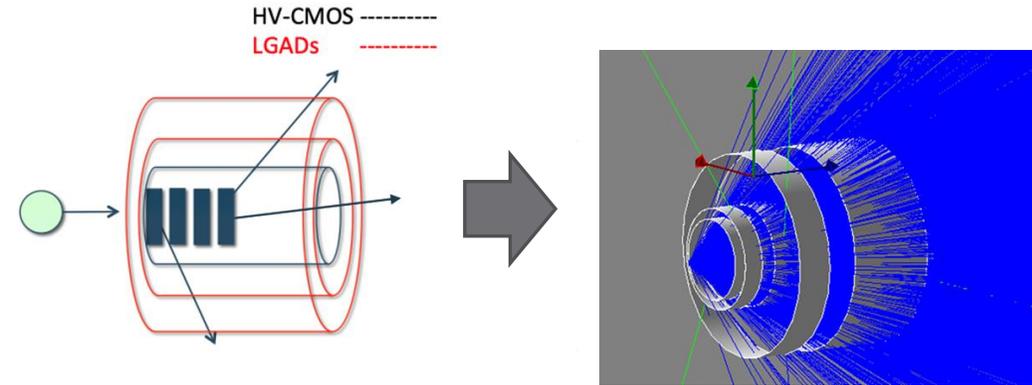

UFSD2 LGAD

Low energy polarimeter

- Simulation

- Assumed LGAD time resolution 30-50 ps
- A suitable energy resolution of 3% can distinguish between elastically scattered events that can be used for the
- Determine suitable flight length for polarimeter application

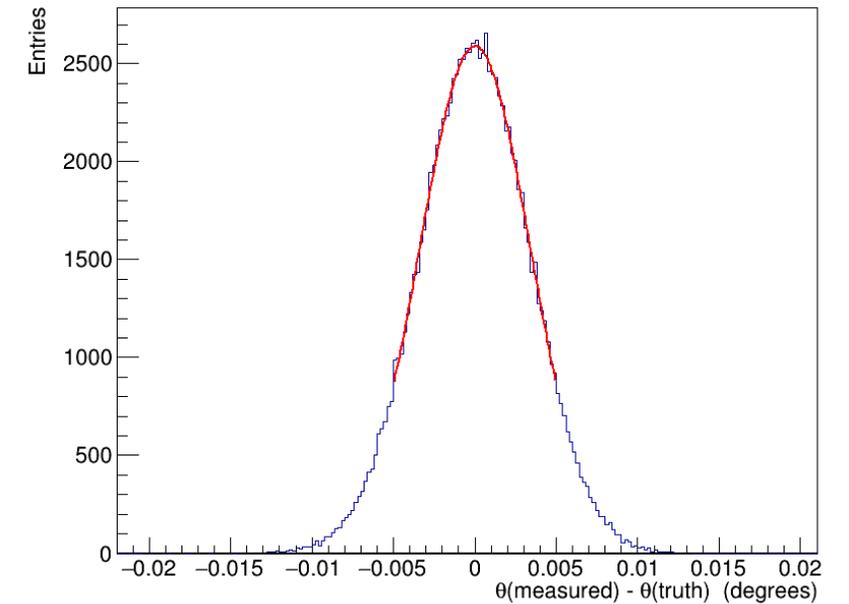

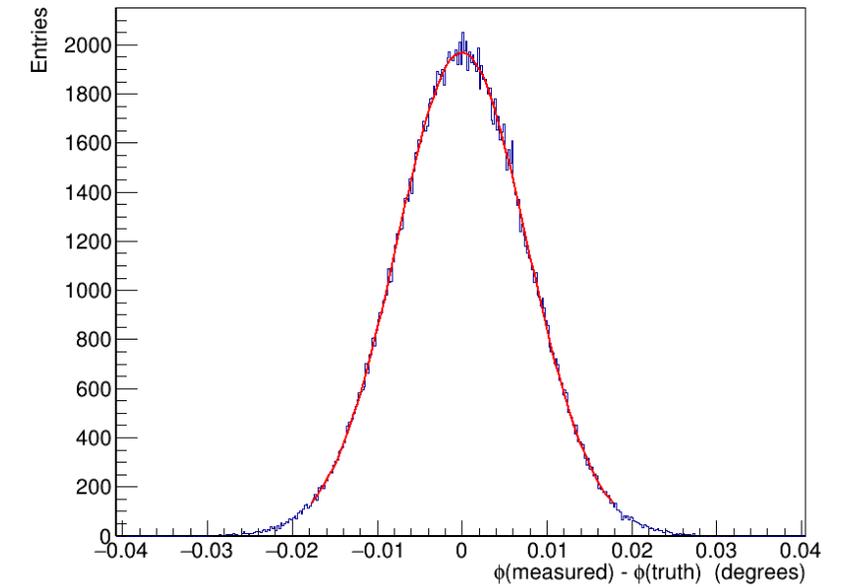

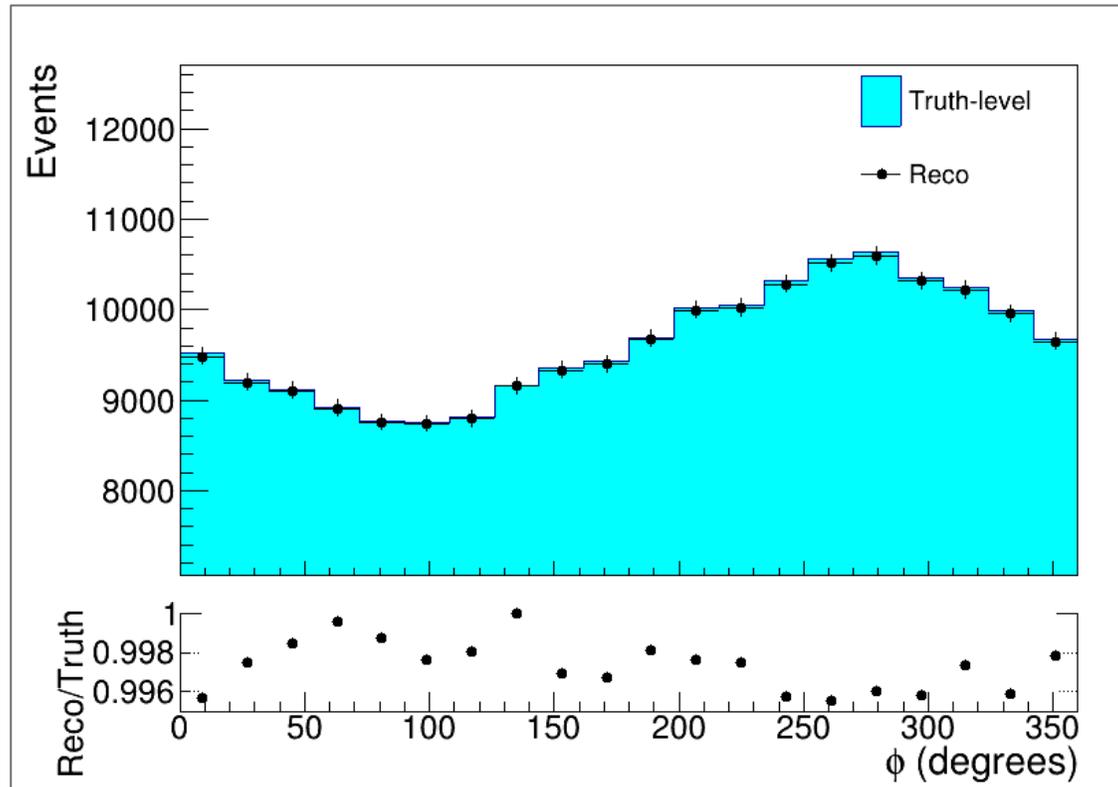

Low energy polarimeter

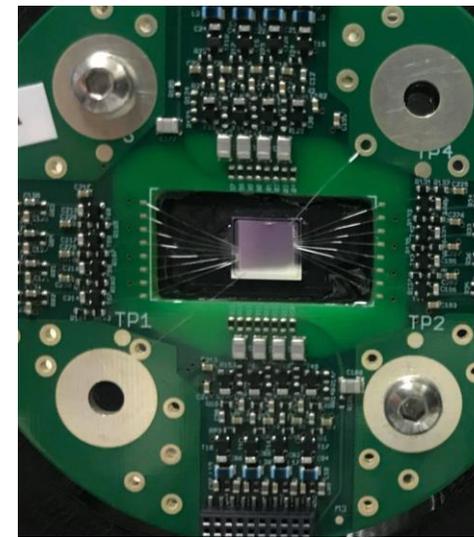

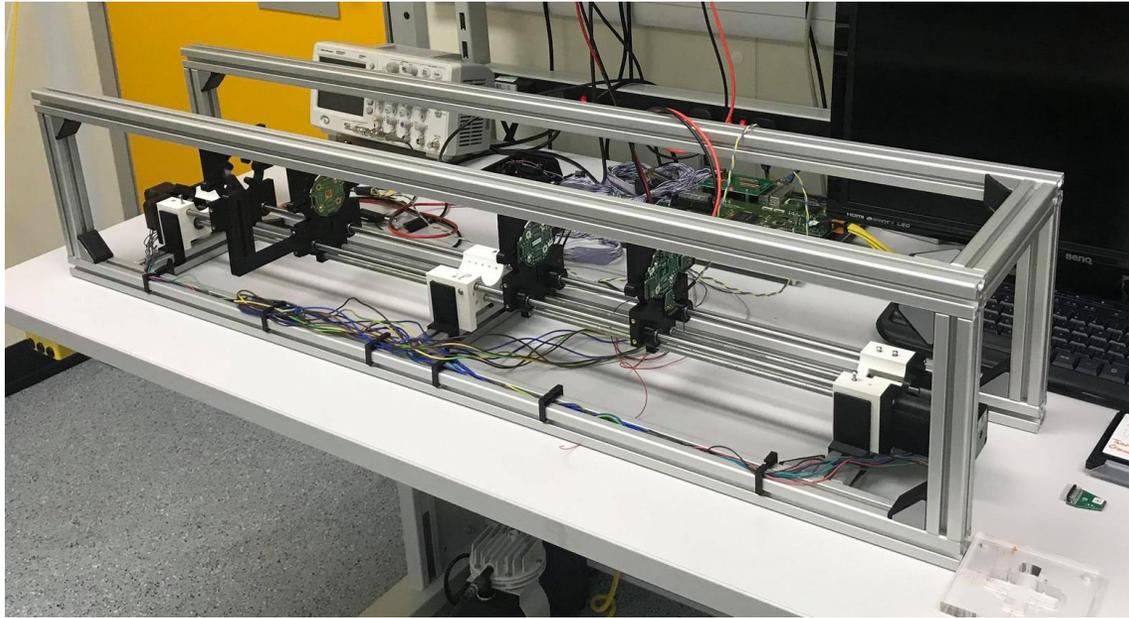

- Simulated Position Resolution

No strict angular resolution is needed (current detector has 1mm resolution)

Position layers help with tracking for energy measurement and give excellent angular resolution regardless

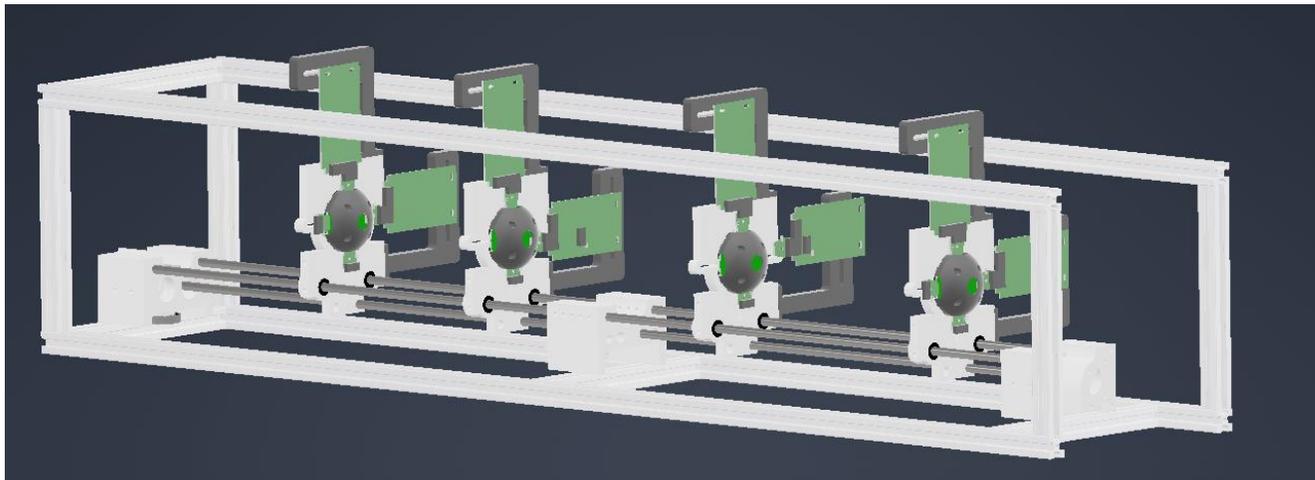

LGAD Time of Flight telescope

LGAD sensors are USFD2 provided by FBK

Two variations:

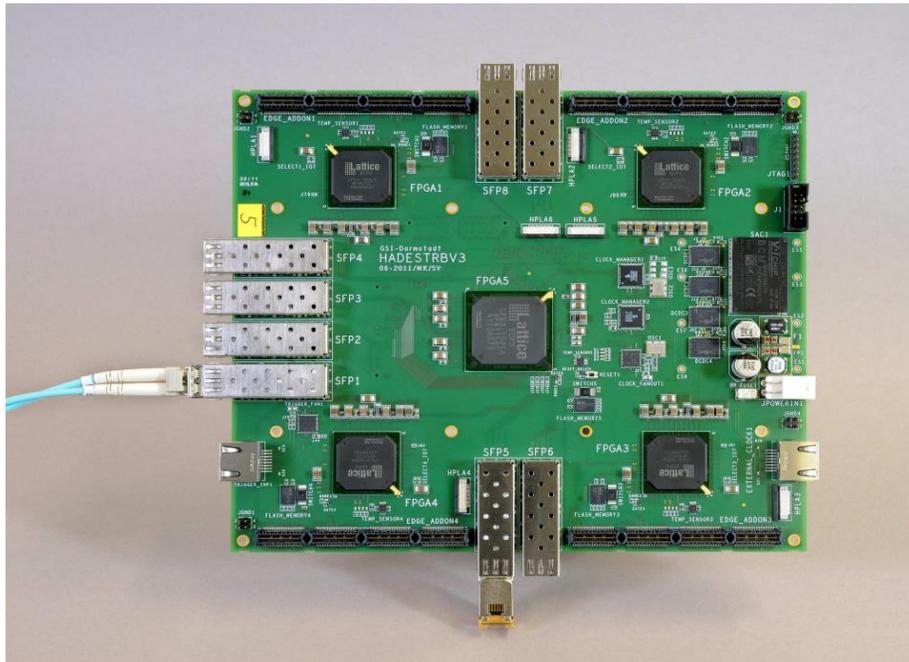

- 30 strip, 146 μm pitch, 5 mm length
- 20 strip, 216 μm pitch, 15 mm length

LGAD Time of Flight telescope

- Readout

TRB3 TDC module

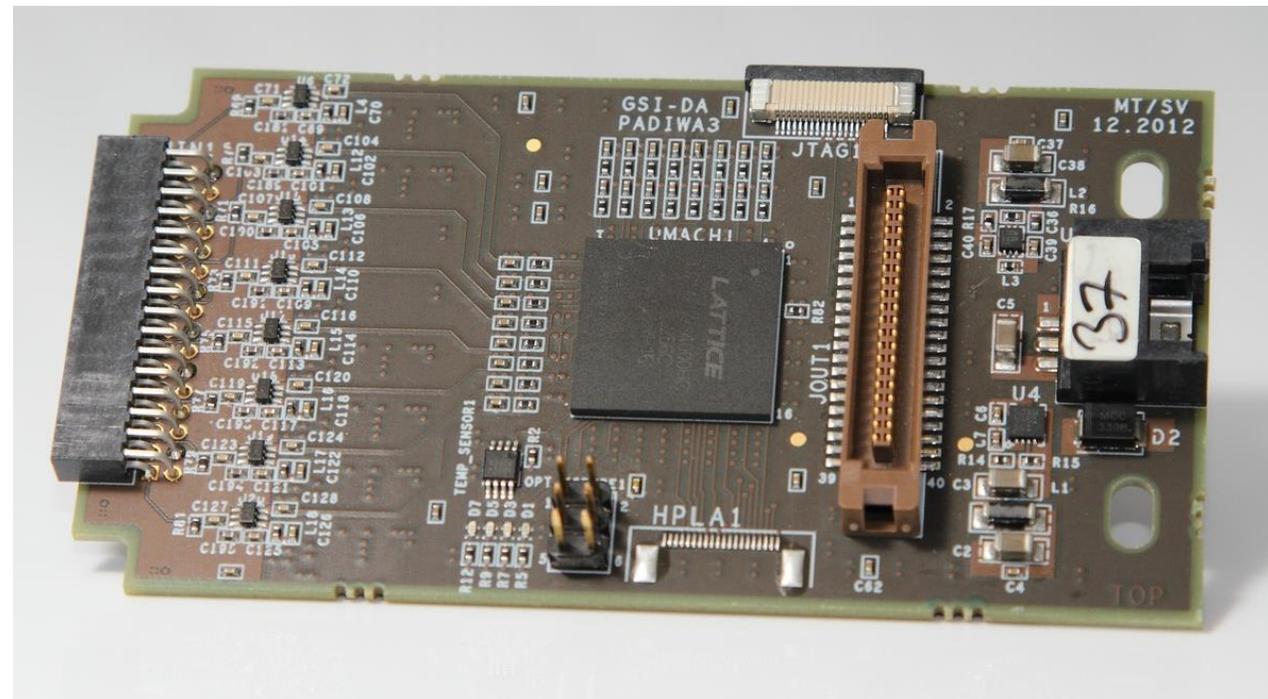

M Traxler et al 2011 JINST 6 C12004

The third addition to Padiwa-family boards, optimized for direct connection to a MC-PMT - four of these 16 channel boards fit onto the 5x5 cm² backside of a typical MC-PMT

LGAD Time of Flight telescope

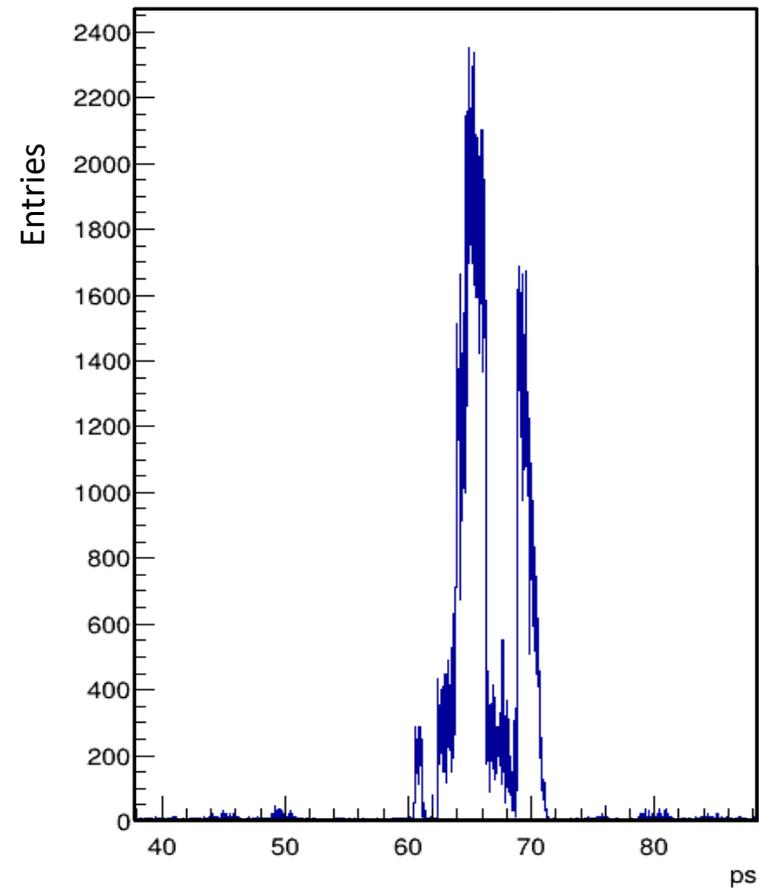

- Sr90 testing

- Initial testing with a strontium-90 beta source
- Good signals pre-amplified on sensor carrier PCB
- Signals have a good enough SNR for input into PADIWA readout

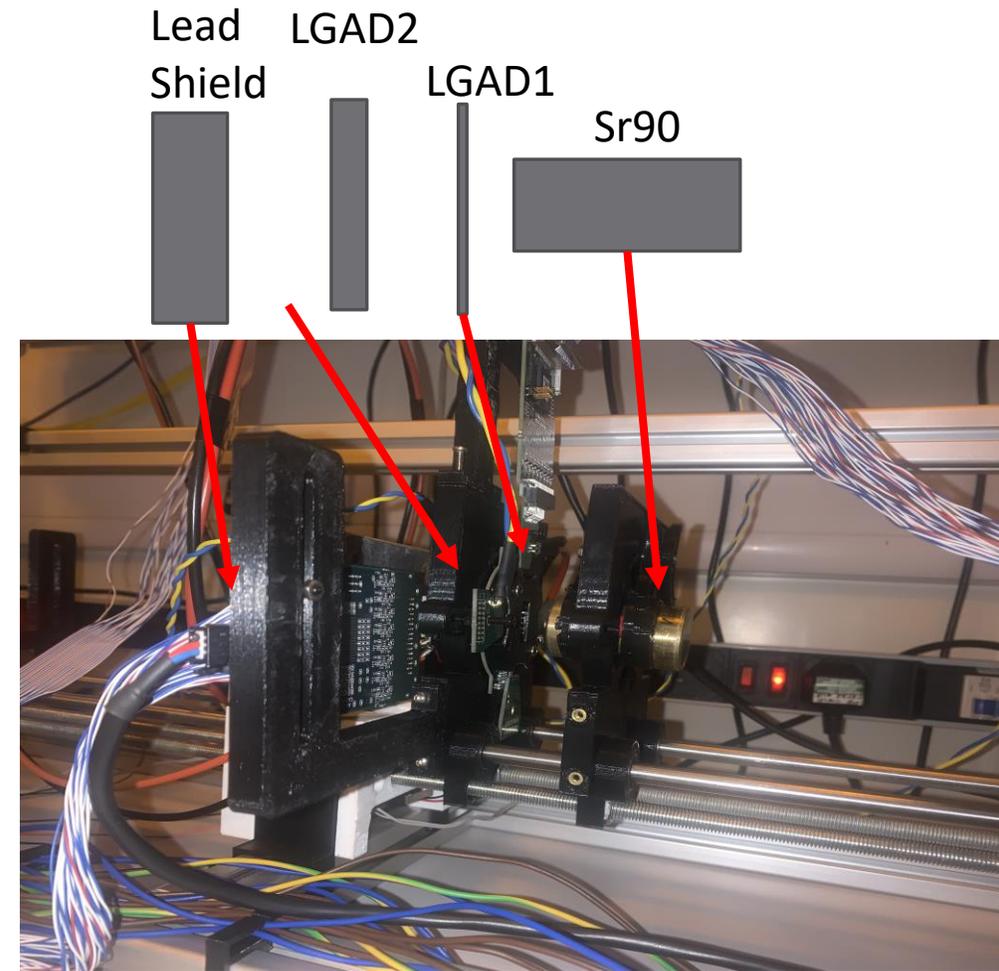

LGAD Time of Flight telescope

- Sr90 testing

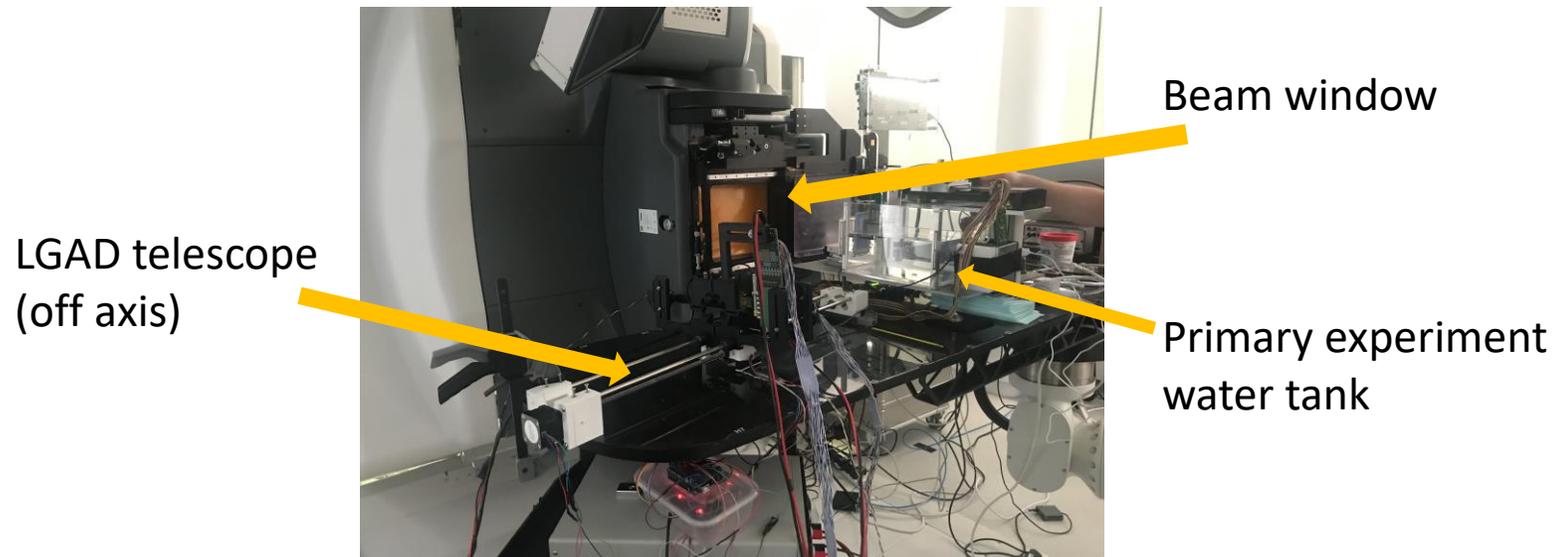

Coincidence results of Sr90 between two layers positioned only 10mm apart.

LGAD Time of Flight telescope

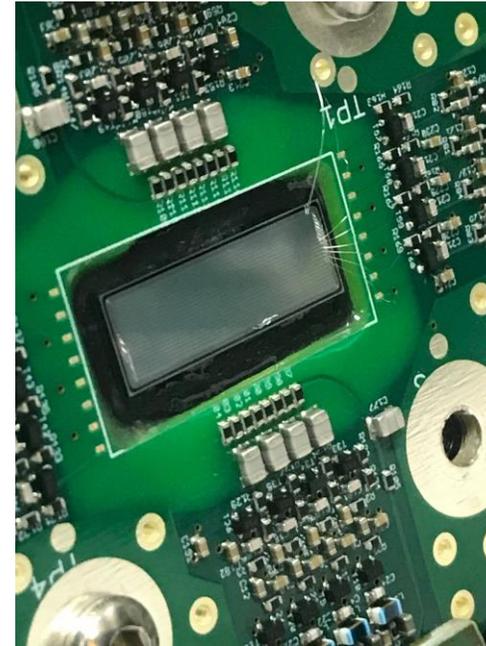

- Testbeam and particle ID

- Using spare (out of hours) proton beam time at Rutherford PLC Cancer Treatment centre in Northumberland
- First testbeam measurements with the LGAD ToF telescope was conducted
- Results currently being analysed
- Poor placement for direct proton measurement
- Telescope observed particles with different time over threshold times possibility that our detectors observed many types of particles and particle identification could be preformed

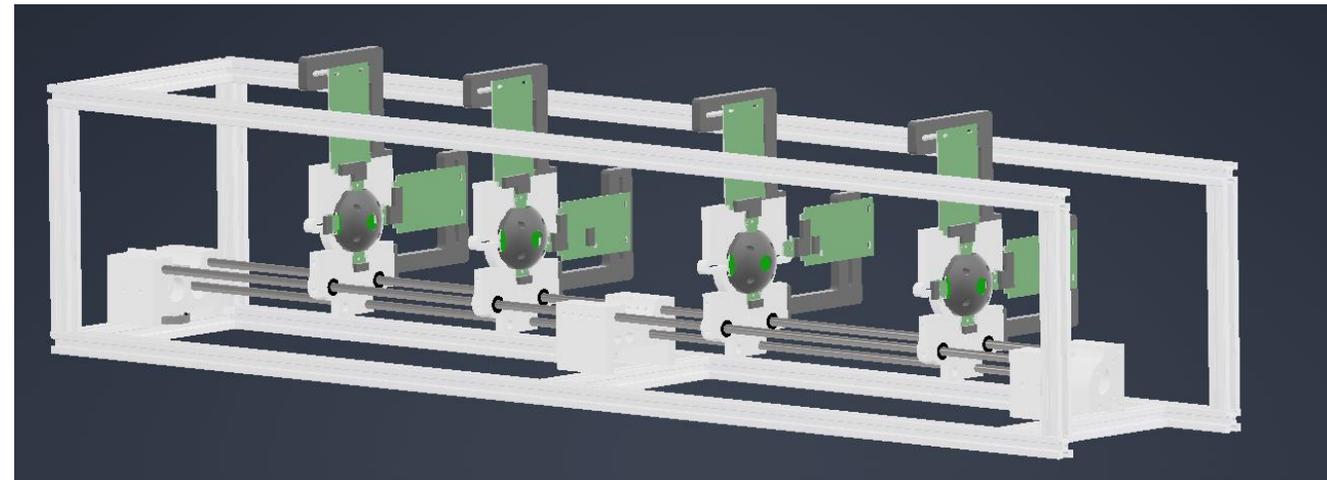

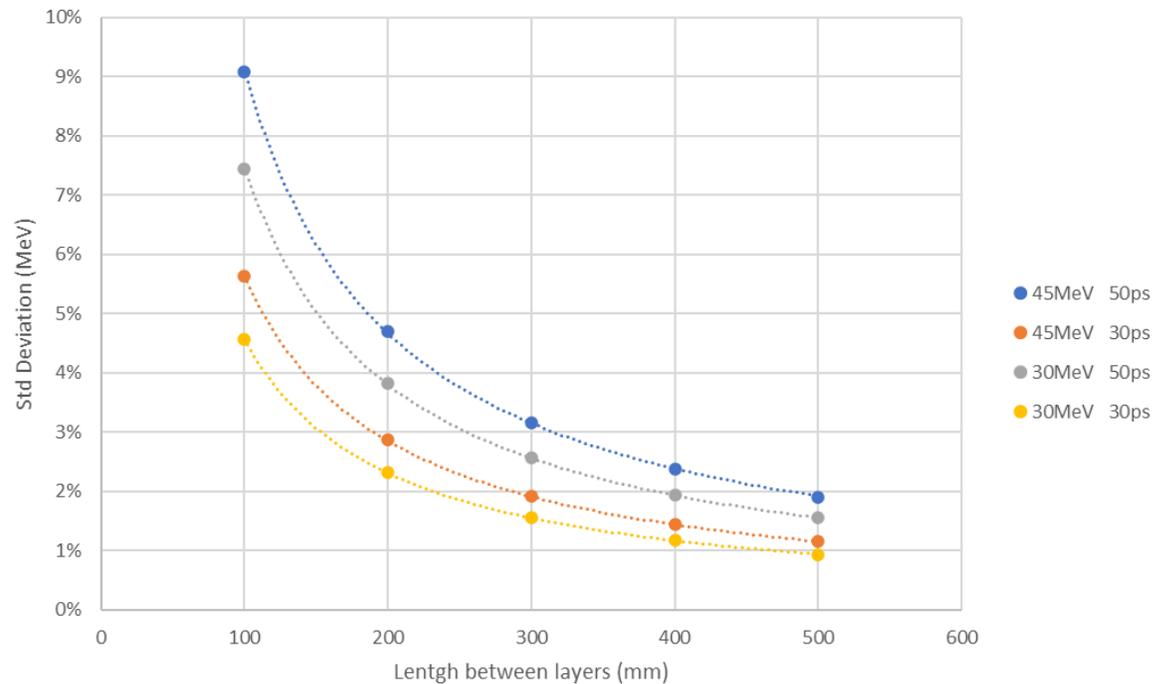

Thank you for listening!

Any Questions?

Error associated with ToF length

Secondary beam polarimeter via pellet target

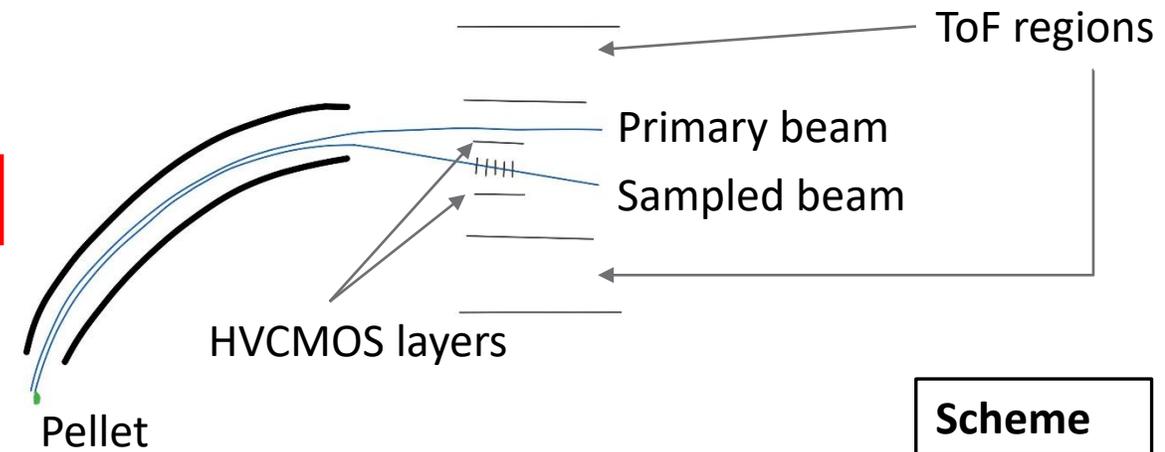

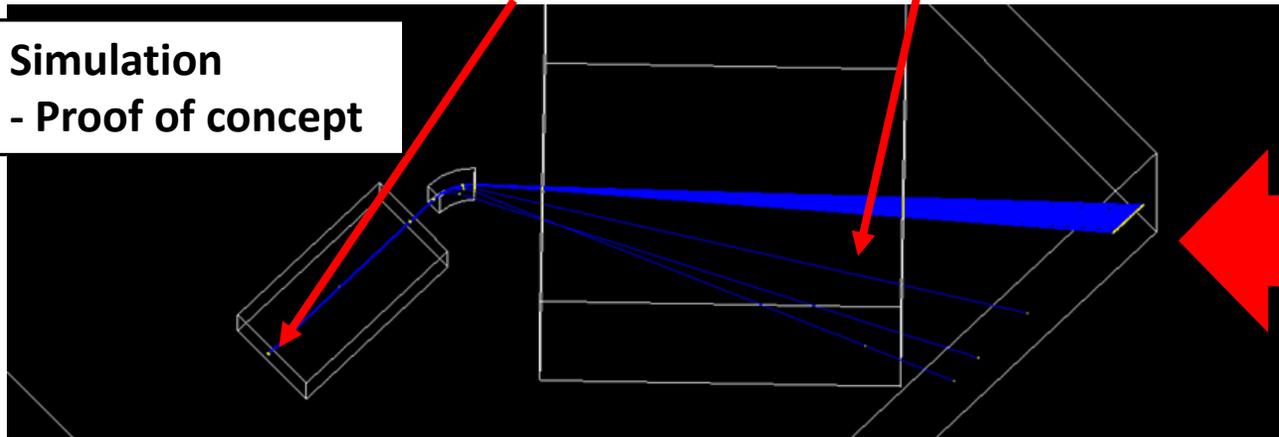

– Influence on primary beam

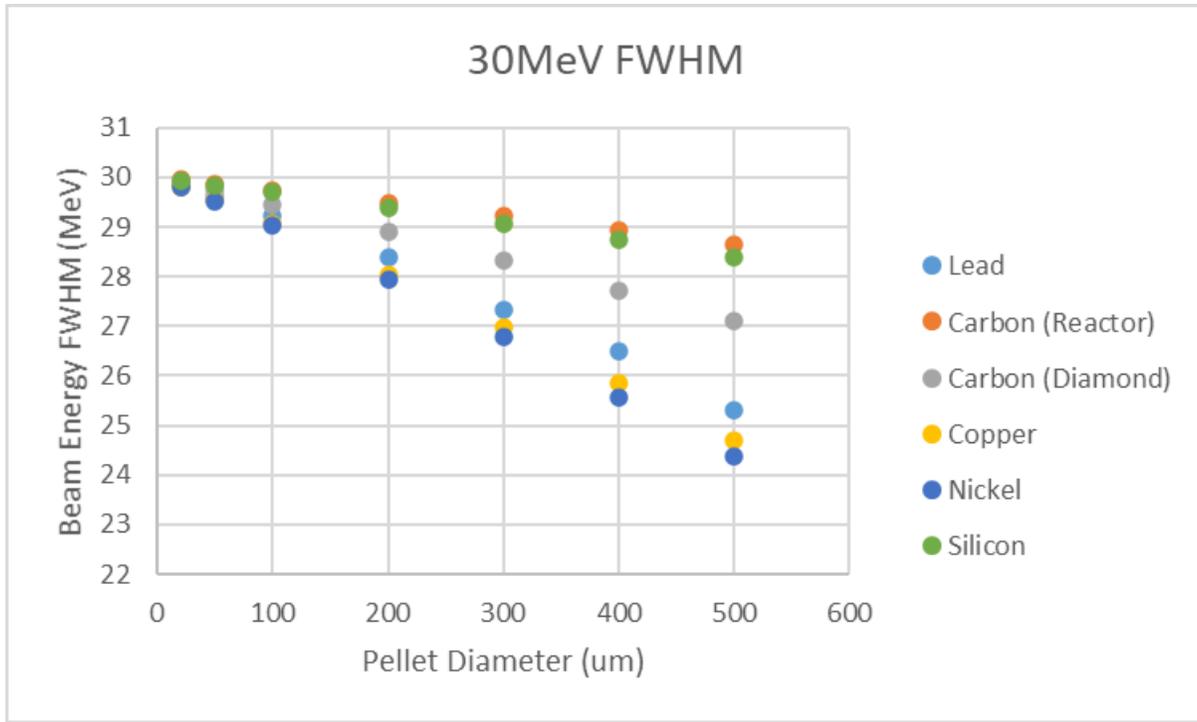

Sampled particles fall slightly out of orbit

Tiny carbon pellet 20 μm

Simulation
- Proof of concept

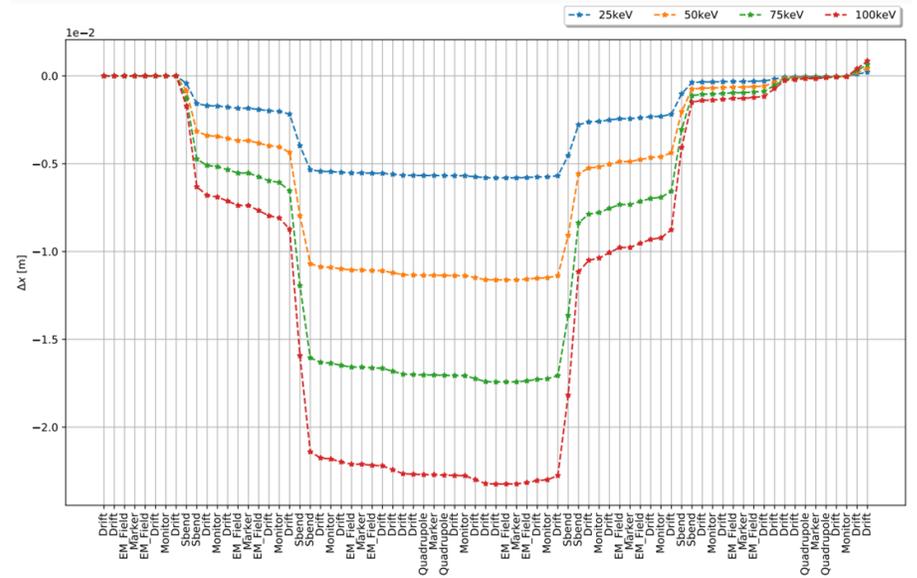

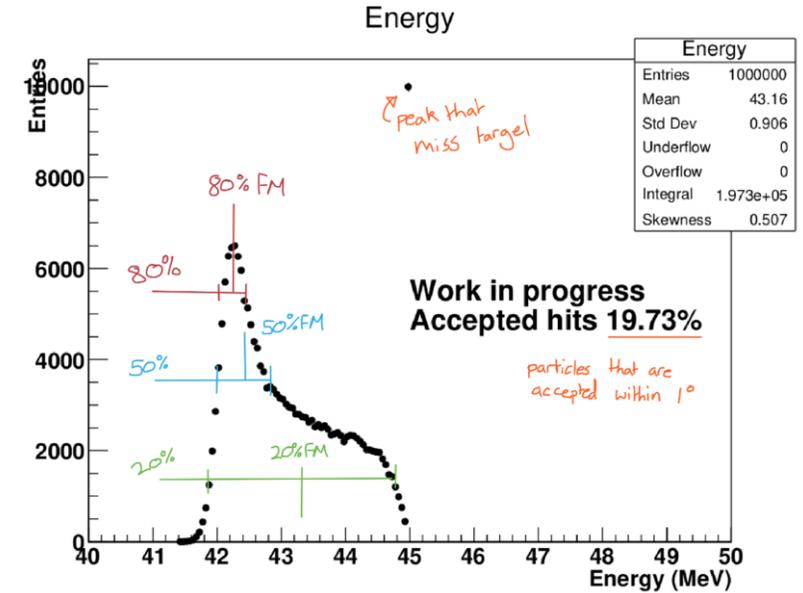

Pellet target feasibility study

Result:

- Pellet target can achieve 2cm offset from main beam whilst retaining stable circulation (100 keV loss in target)

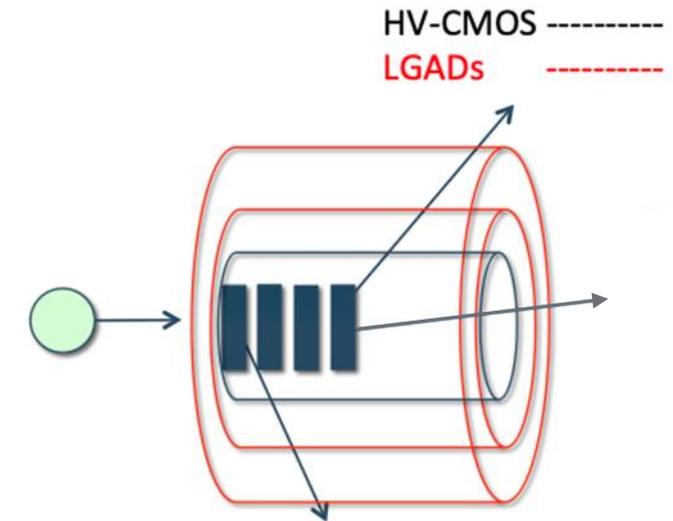

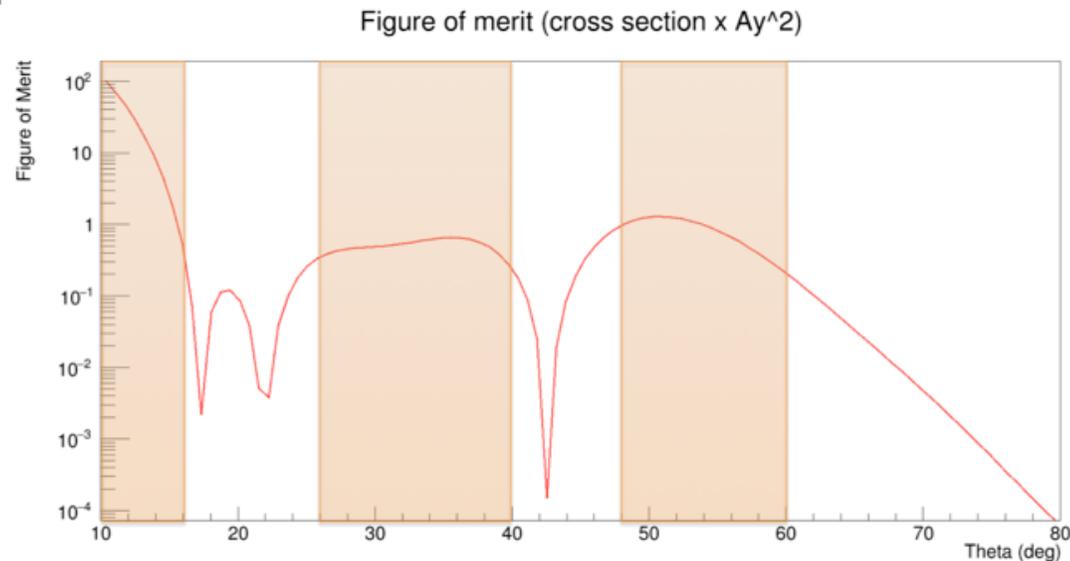

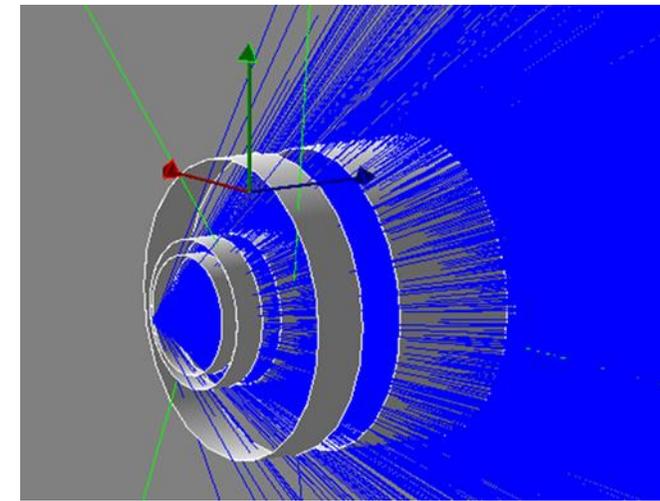

Simulations by Maximilian Vitz

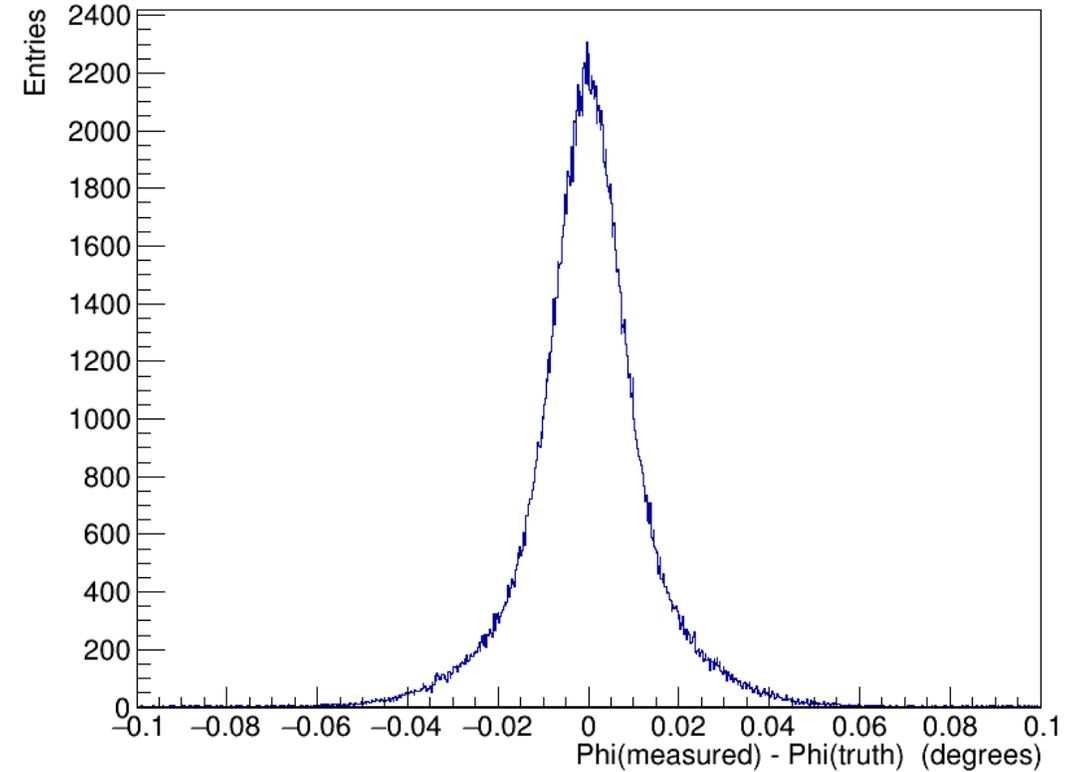

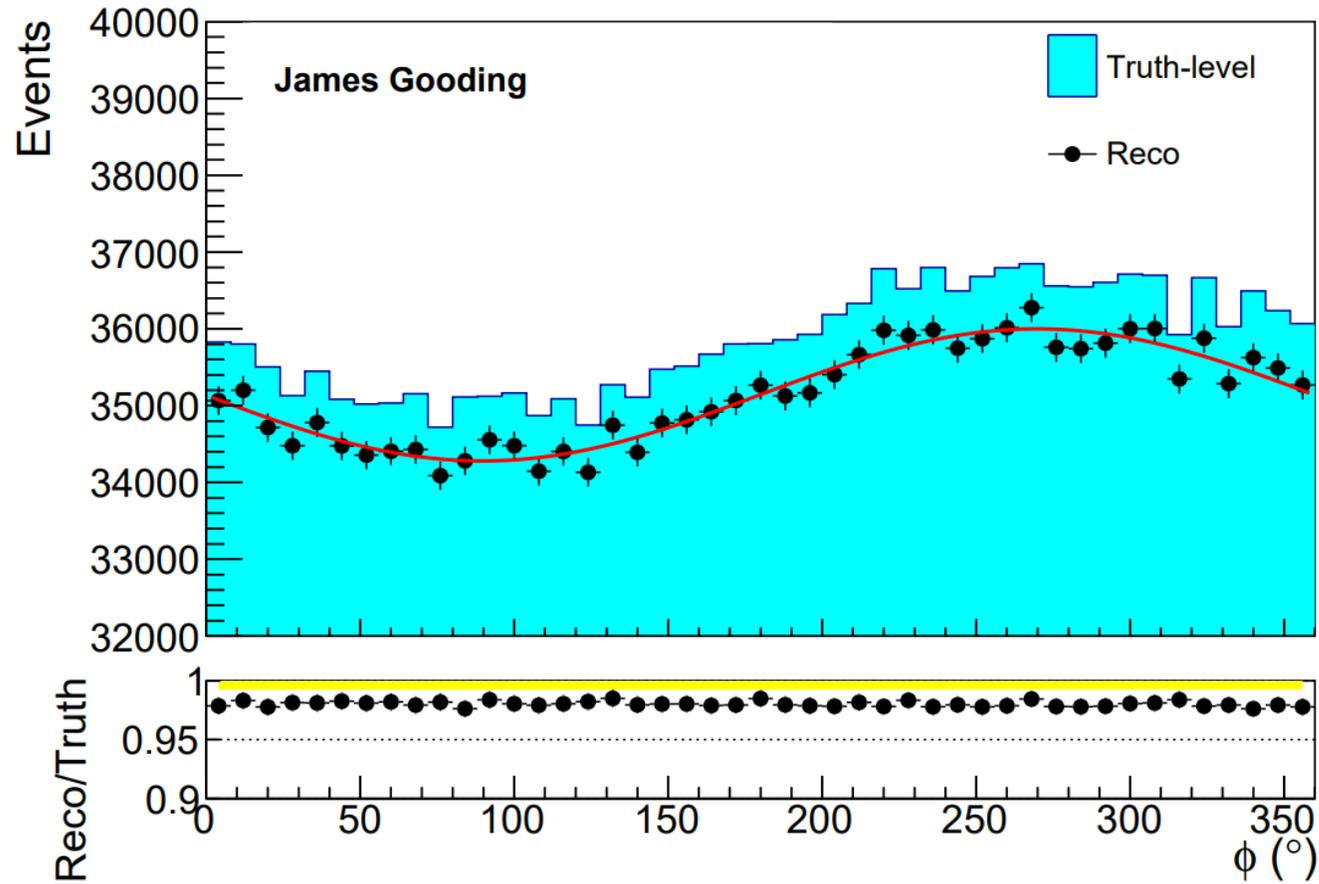

Configuration

A forward configuration will target only one area of figure of merit

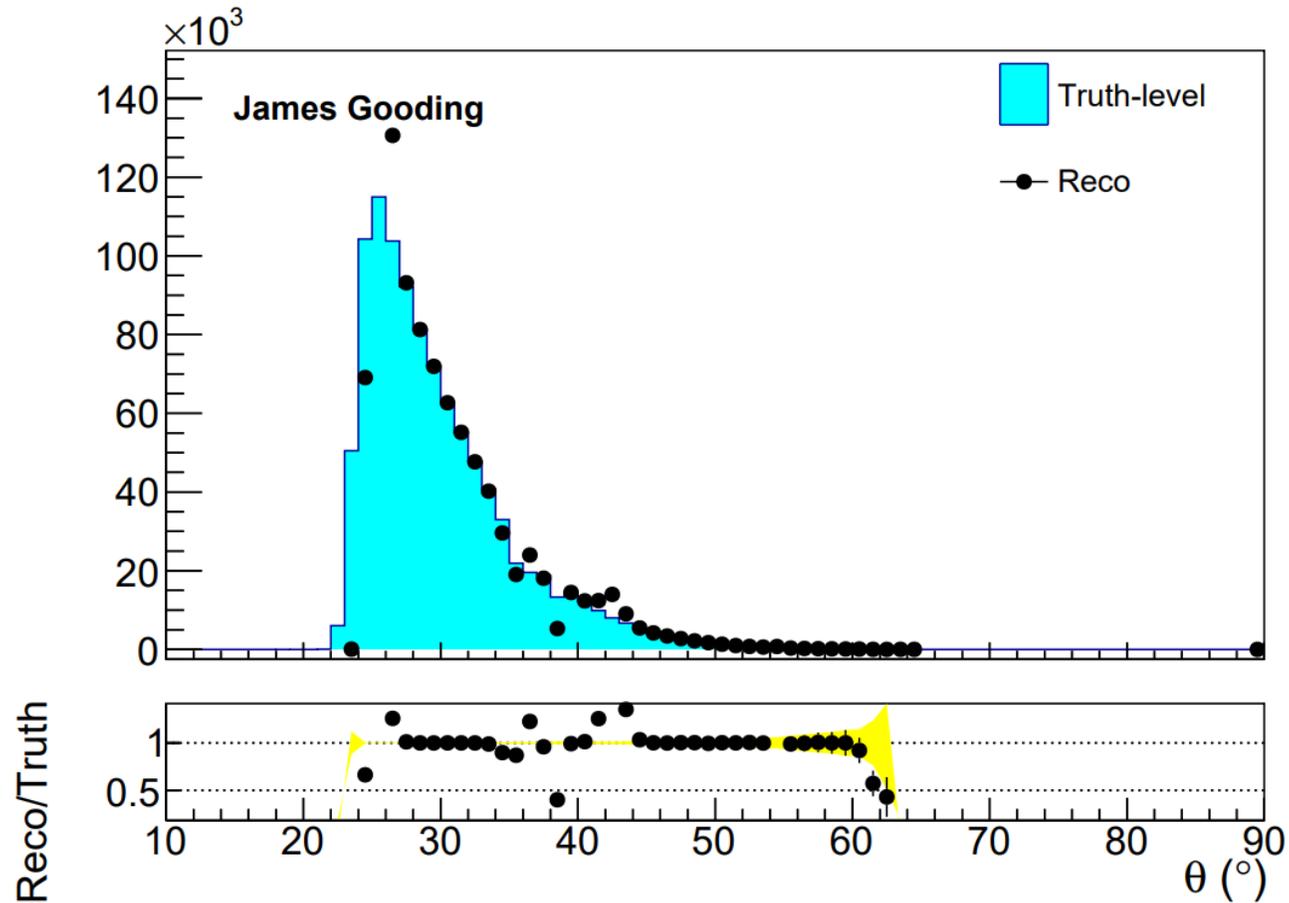

- A cylindrical design surrounding the beamline and target will be effective in two areas of high figure of merit.
- Forward area figure of merit strongly influenced by rate, not analyzing power.

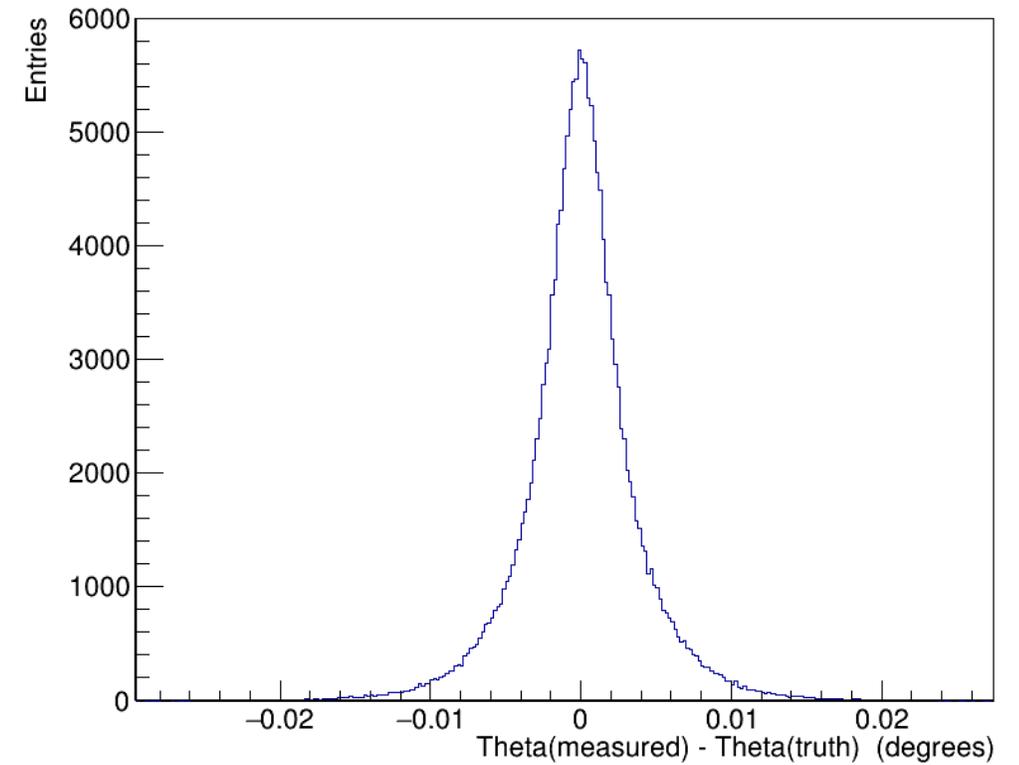

Phi measurement accuracy and efficiency

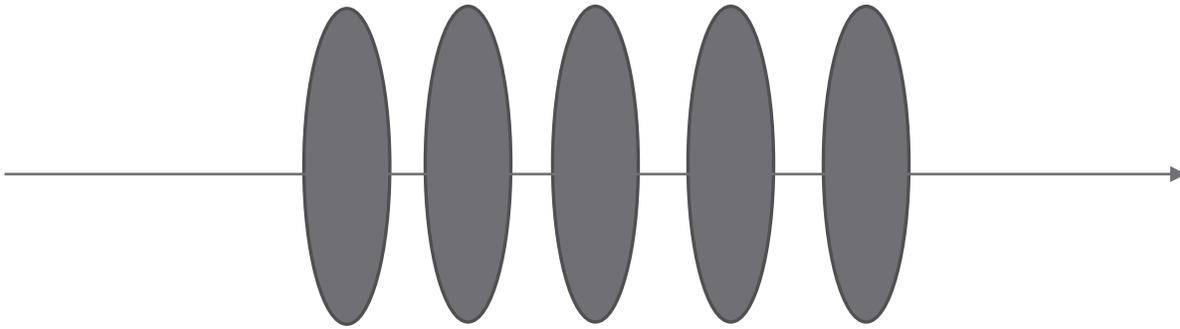

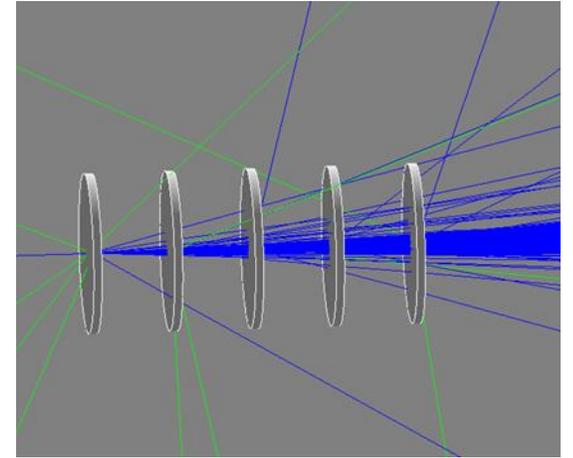

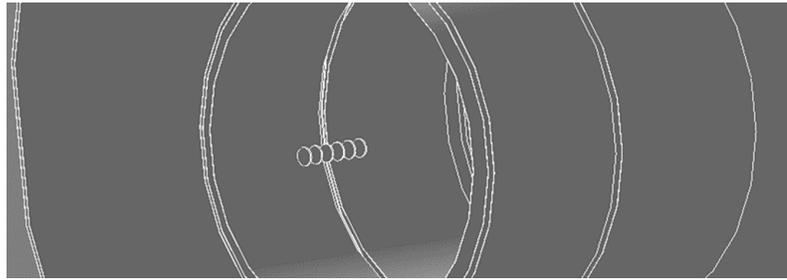

Theta accuracy and efficiency

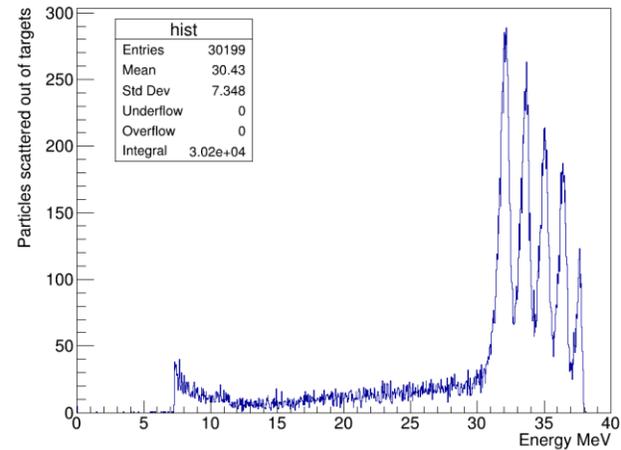

Some theta sections struggle to be reconstructed in sections where there is spacing between cylinders.

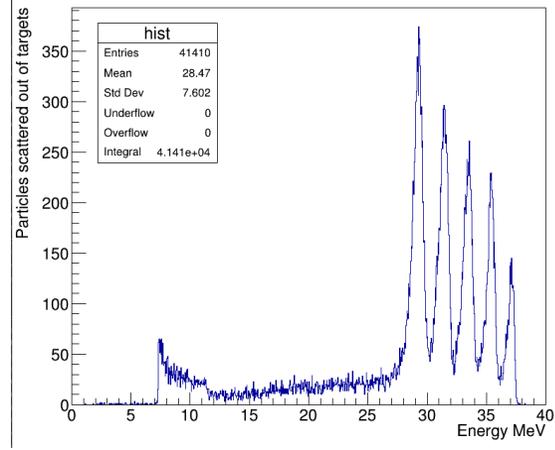

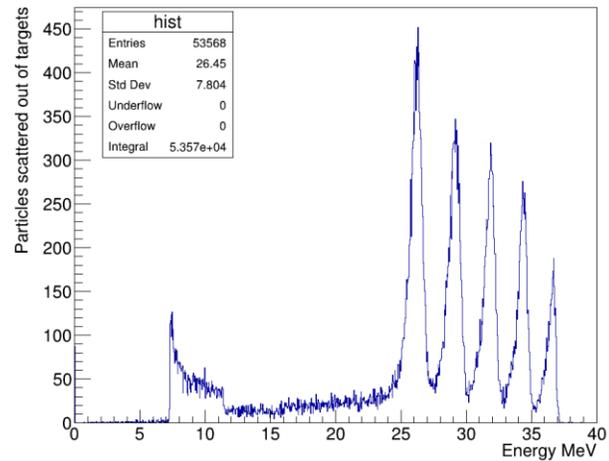

600um thick carbon targets (5mm radius, 15mm spacing)

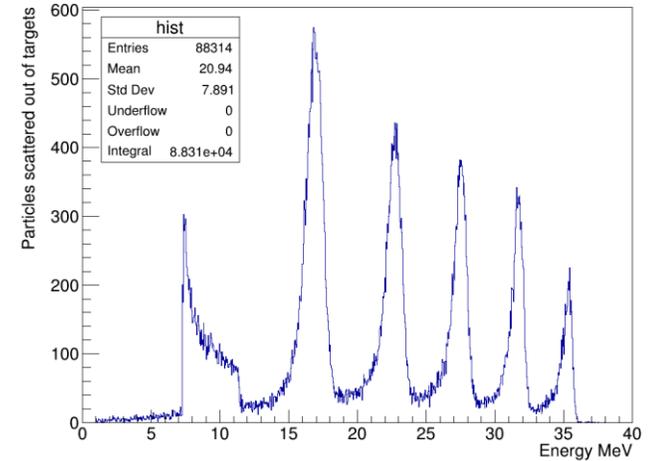

800um thick carbon targets (5mm radius, 15mm spacing)

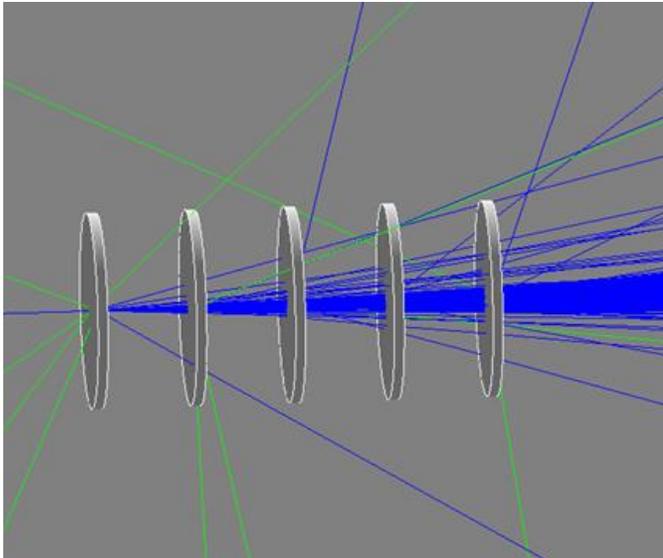

1000um thick carbon targets (5mm radius, 15mm spacing)

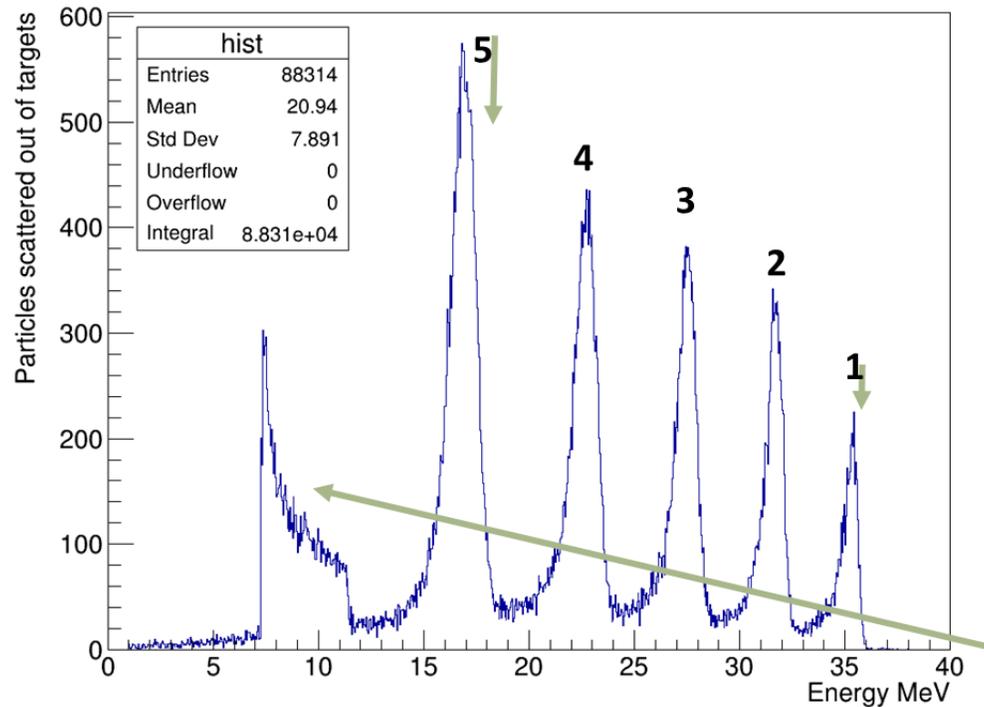

1500um thick carbon targets (5mm radius, 15mm spacing)

Split Target Investigations

1500um thick carbon targets (5mm radius, 15mm spacing)

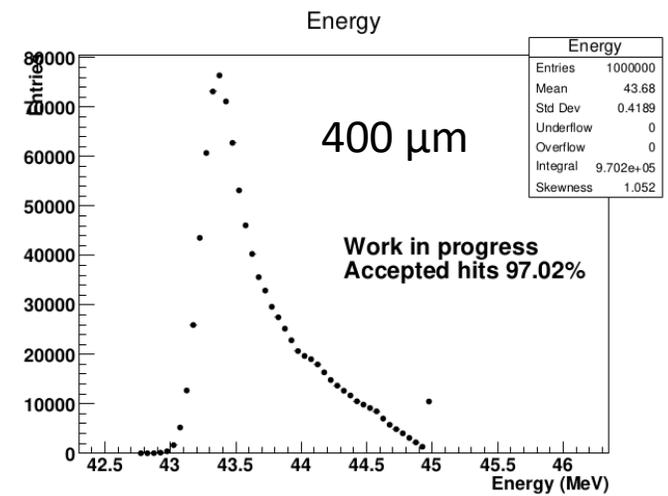

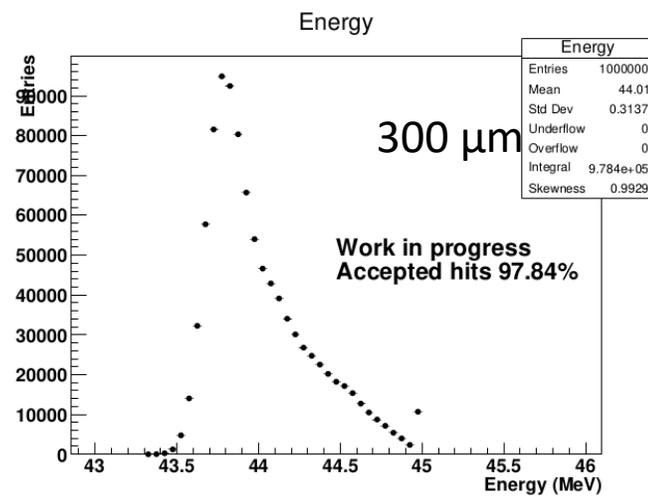

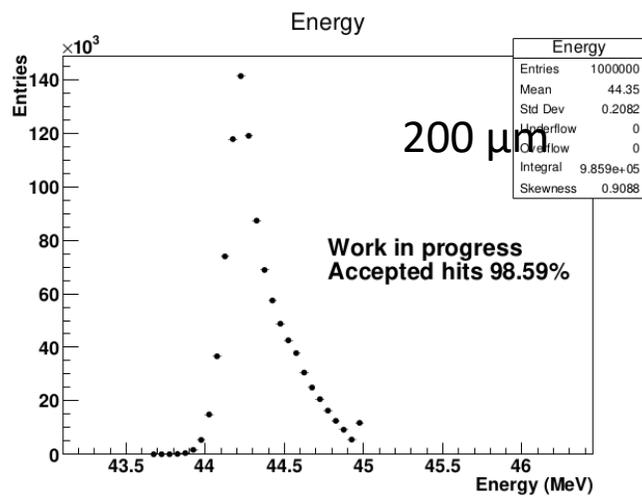

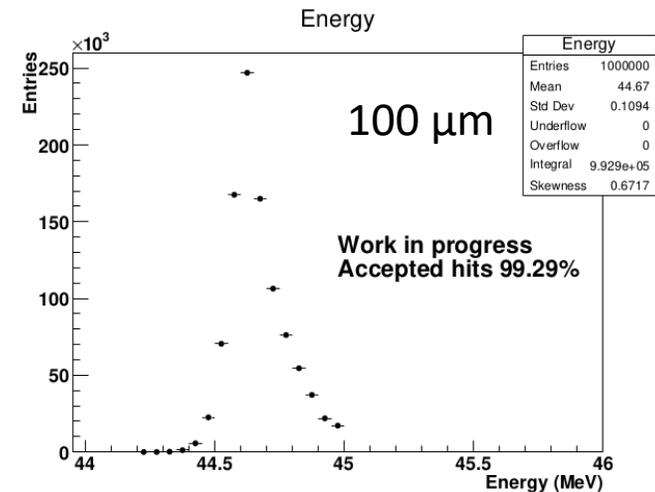

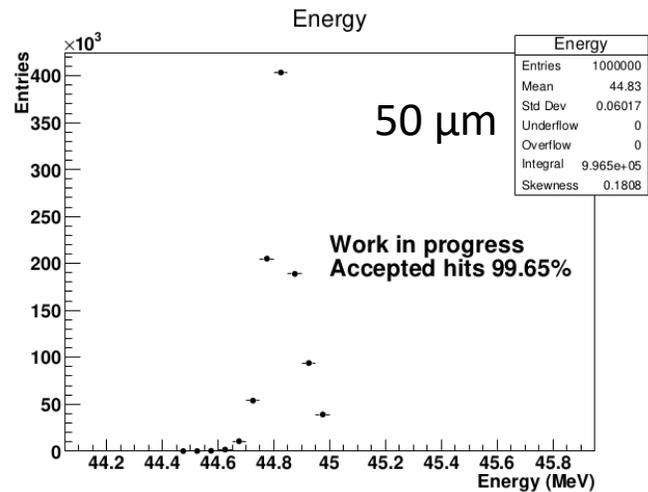

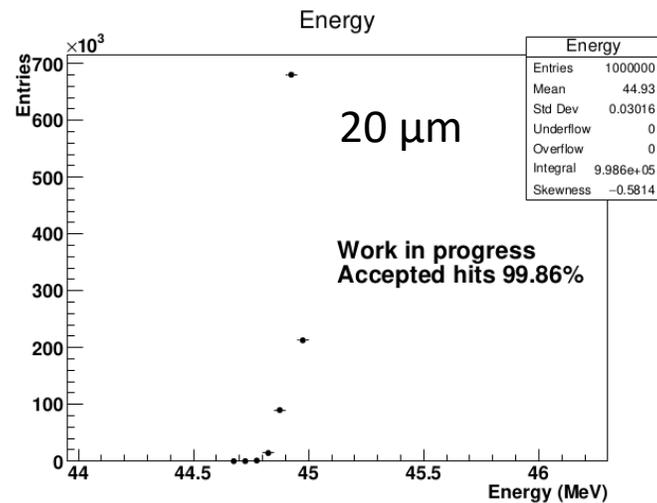

Scatter from last target

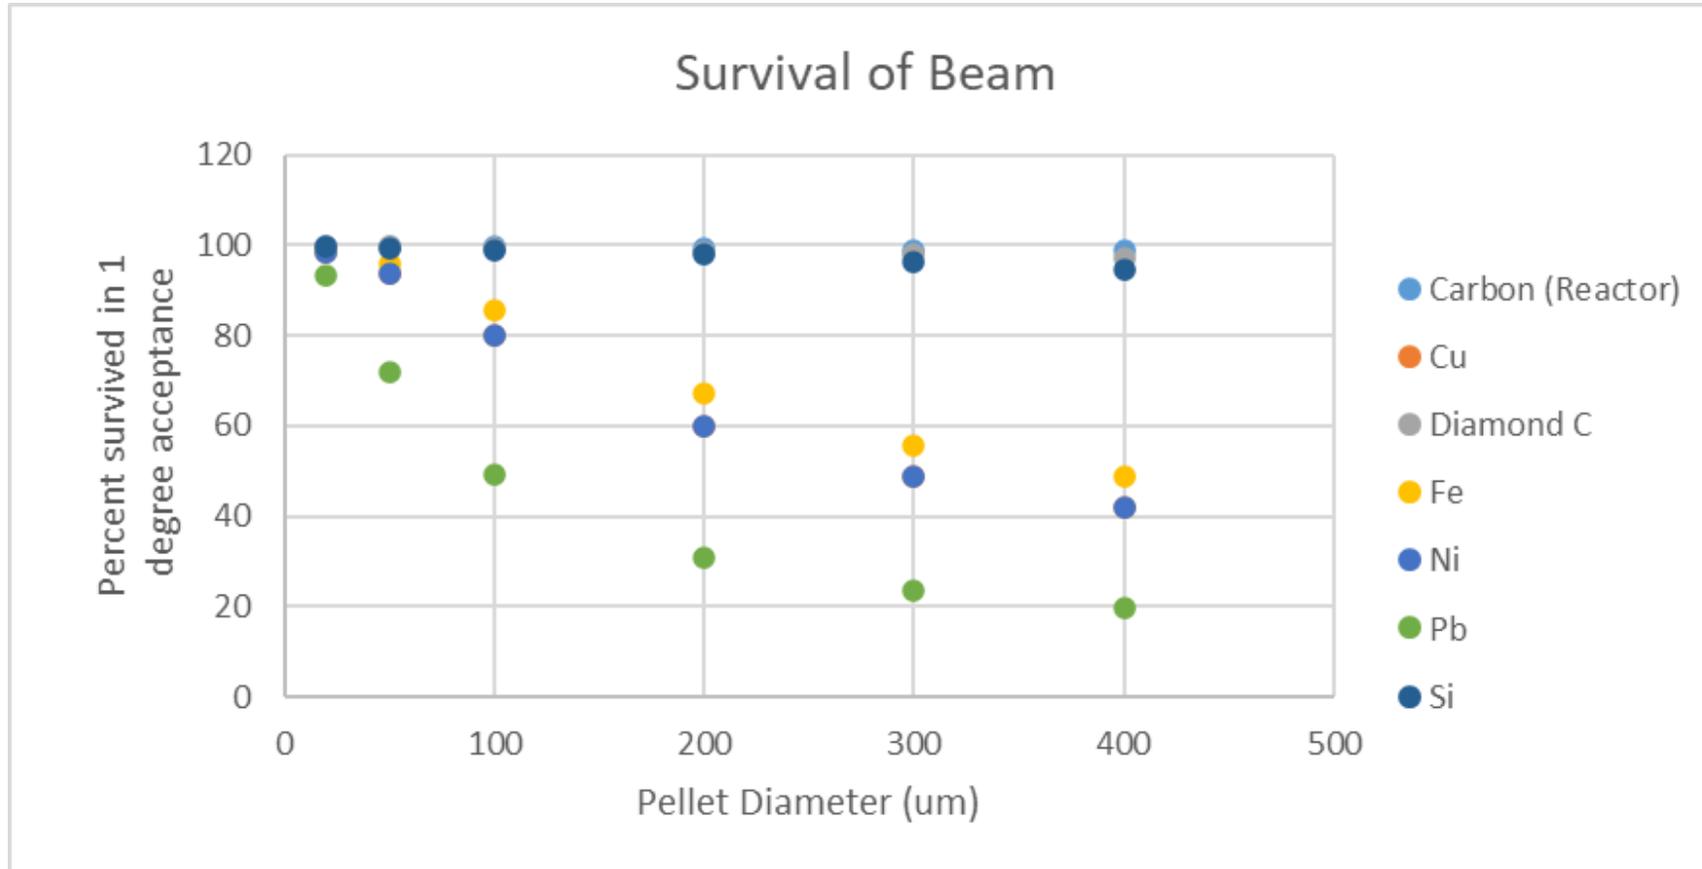

Scatter from first target

Inelastic landau region
(Proportional to thickness)
(Seems to be radius independent on first testing)

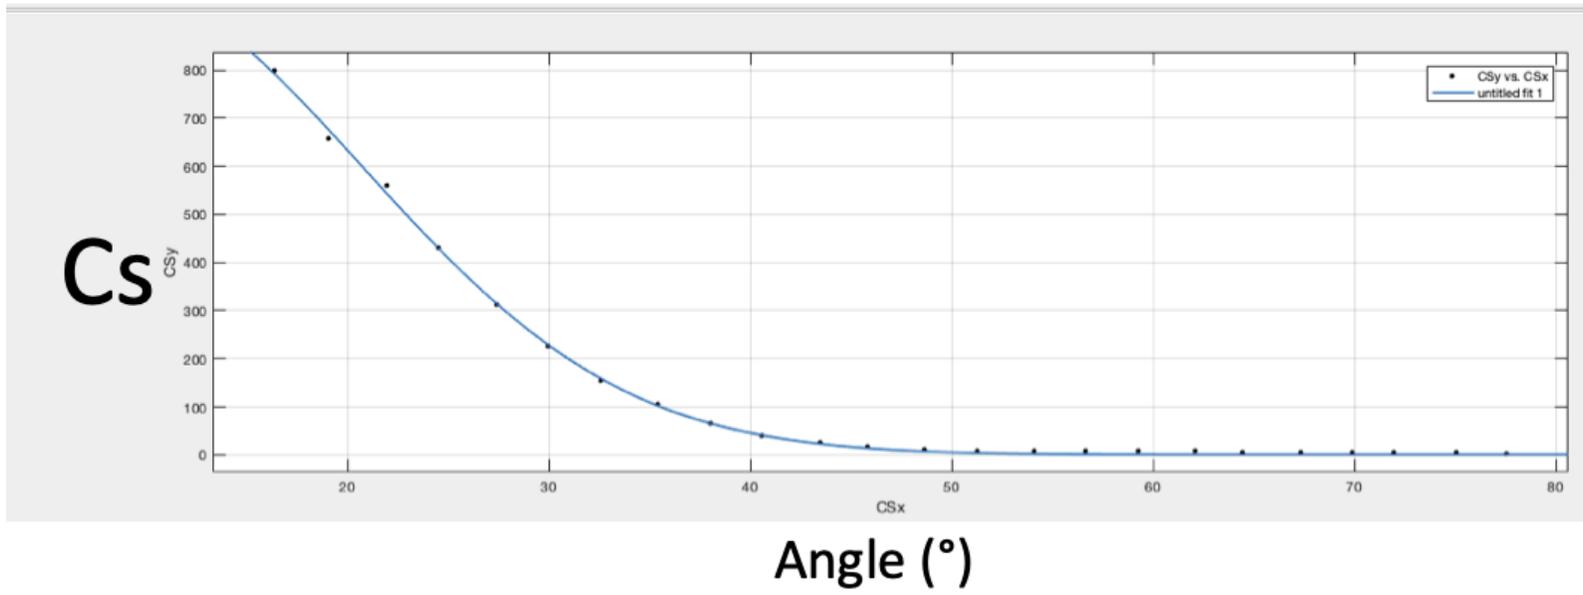

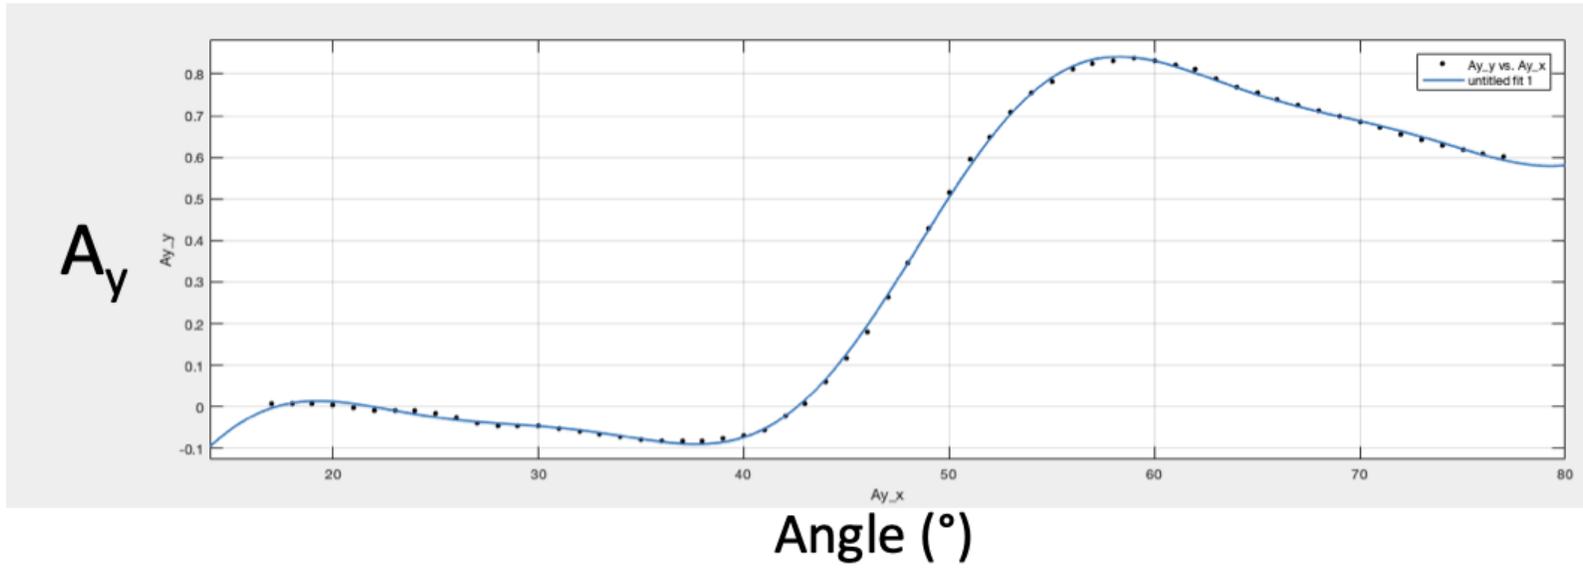

Carbon (Diamond) 45MeV

30 MeV

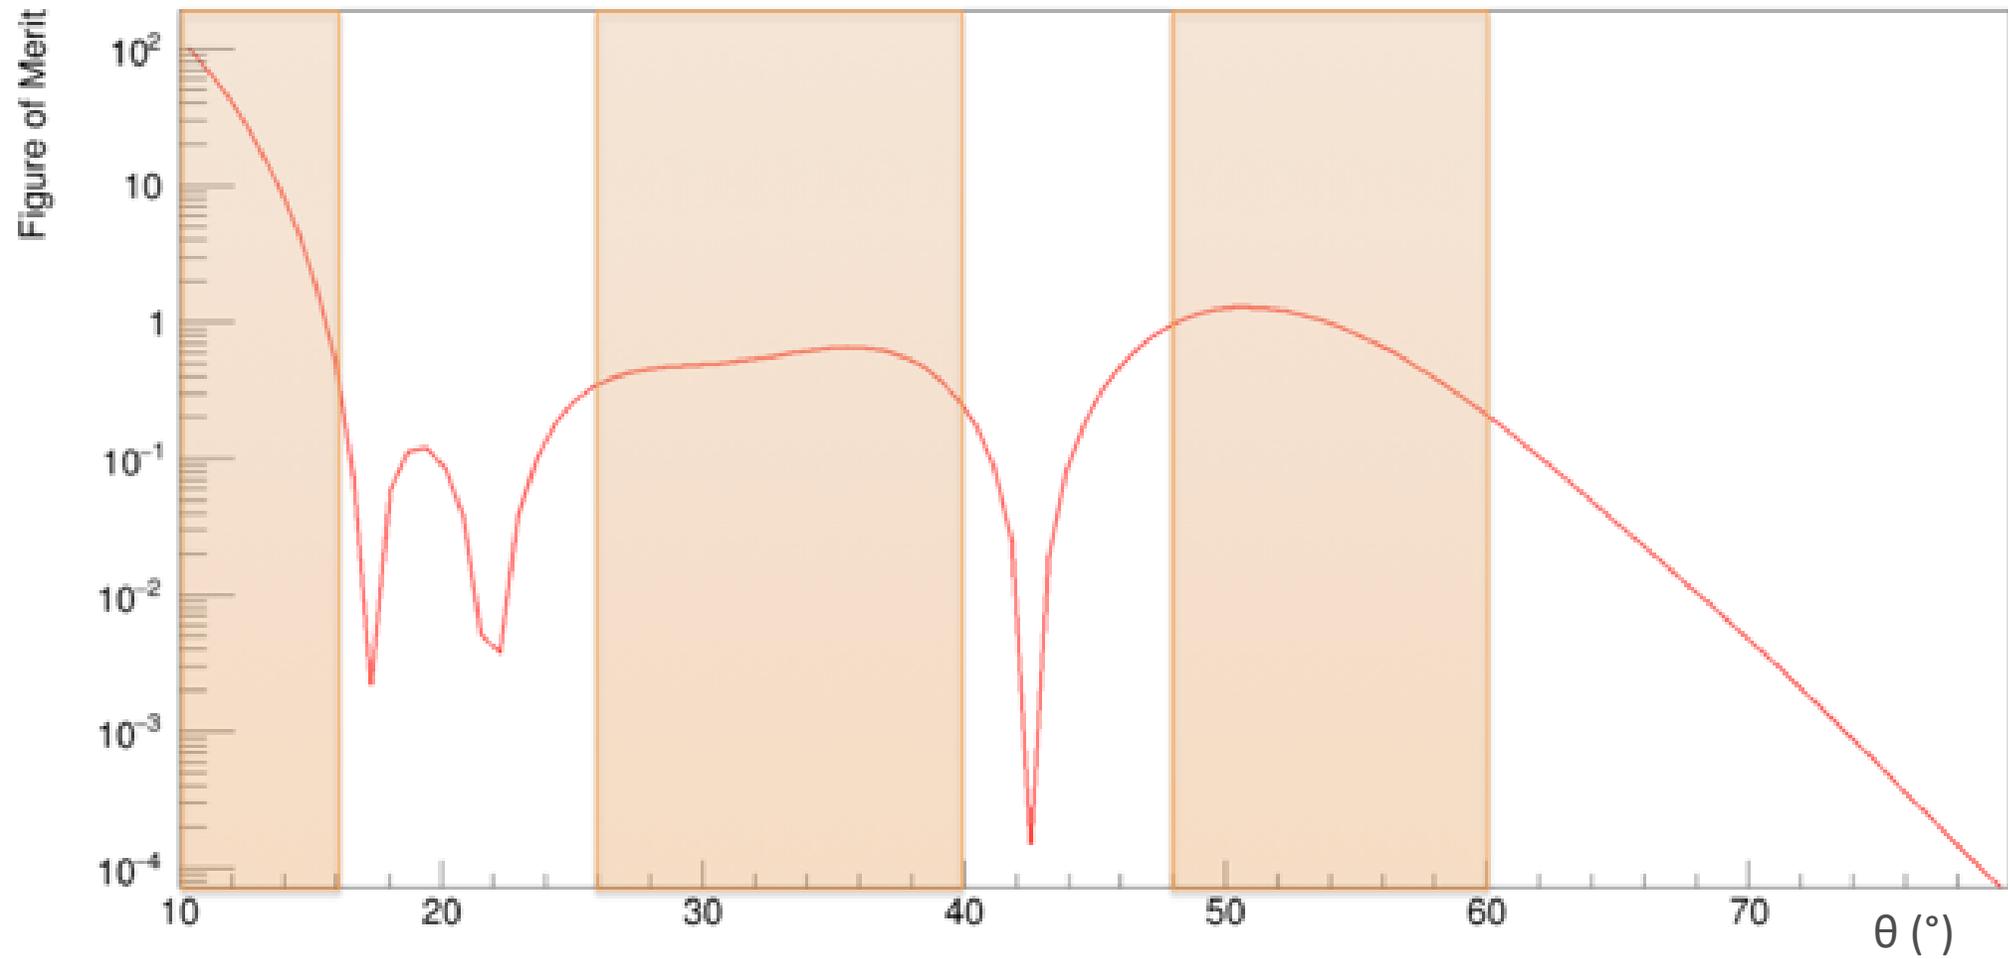

Beam defined as 1% larger diameter than pellet:
- 1.97% by definition passes pellet without interaction

39.6 MeV

Figure of merit (cross section $\times A_y^2$)

Price/performance	Due to industry standard processes, they are comparatively cheap for the performance when compared to conventional hybrid sensors.
Signal output	Due to in-pixel amplification and processing, the signal output from each pixel is very high and well digitized.
Signal/noise ratio	Low leakage current as well as in pixel amplification causes a high signal-to-noise ratio.
Fill factor (FF)	The readout electronics can be integrated in the sensing area of the pixels which leads to a fill factor close to 100\% although some components such as bias blocks, voltage regulators and I/O pads cannot be built into the sensitive area.
Time resolution	Good timing resolution, up to 5 ns after timing corrections has been achieved.
Radiation tolerance	Large depletion voltages can be used. This leads to fast collection of charge carriers from the depleted area which causes the sensors to be less susceptible to radiation damage allowing radiation tolerance of $10^{15} \text{ n}_{\text{eq}}\text{cm}^{-2}$.
