Jeff Hyde

Pheno 2019 – May 7, 2019

Based on [arXiv:1806.09221](https://arxiv.org/abs/1806.09221) & on-going work

Measuring δ_{13} is a big goal for long-baseline experiments.

In vacuum:

If the probability $P(\nu_\mu \rightarrow \nu_e) \equiv P$ is different from $P(\bar{\nu}_\mu \rightarrow \bar{\nu}_e) \equiv \bar{P}$, then $\delta_{13} \neq 0, \pi$.

In matter:

Propagation through CP-violating potential $V \sim \text{diag}(1, 0, 0)$ generally gives $P \neq \bar{P}$.

Non-standard interactions further complicate things

Beyond-Standard Model physics \rightarrow “Non-standard Neutrino Interactions” (NSI)

e.g. get off-diagonal elements with CP-violating phases:

$$V \sim \begin{pmatrix} 1 + \epsilon_{ee} & \epsilon_{e\mu} & \epsilon_{e\tau} \\ \epsilon_{e\mu}^* & \epsilon_{\mu\mu} & \epsilon_{\mu\tau} \\ \epsilon_{e\tau}^* & \epsilon_{\mu\tau}^* & \epsilon_{\tau\tau} \end{pmatrix} \quad (\epsilon_{e\mu} = |\epsilon_{e\mu}| \exp(-i\delta_{e\mu}), \dots)$$

Non-standard interactions further complicate things

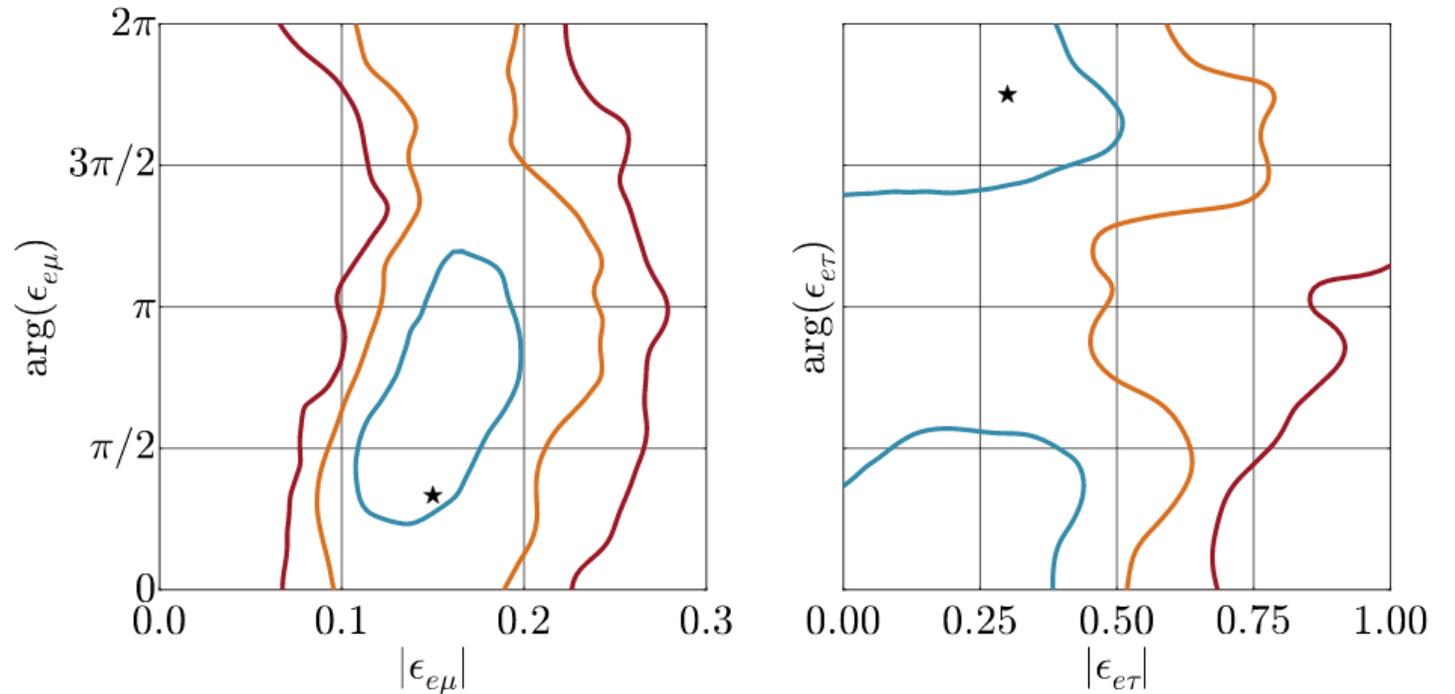

How can we tell whether CP is violated (and determine the underlying parameters) in the presence of nonstandard interactions?

$$V \sim \begin{pmatrix} \epsilon_{e\mu}^* & \epsilon_{\mu\mu} & \epsilon_{\mu\tau} \\ \epsilon_{e\tau}^* & \epsilon_{\mu\tau}^* & \epsilon_{\tau\tau} \end{pmatrix} \quad (\epsilon_{e\mu} = |\epsilon_{e\mu}| \exp(-i\delta_{e\mu}), \dots)$$

It's common to look at sensitivity of given experiments based on specific parameter choices.

e.g. from de Gouvea & Kelly
Nuclear Phys. B908 (2016)
arXiv:1511.05562,

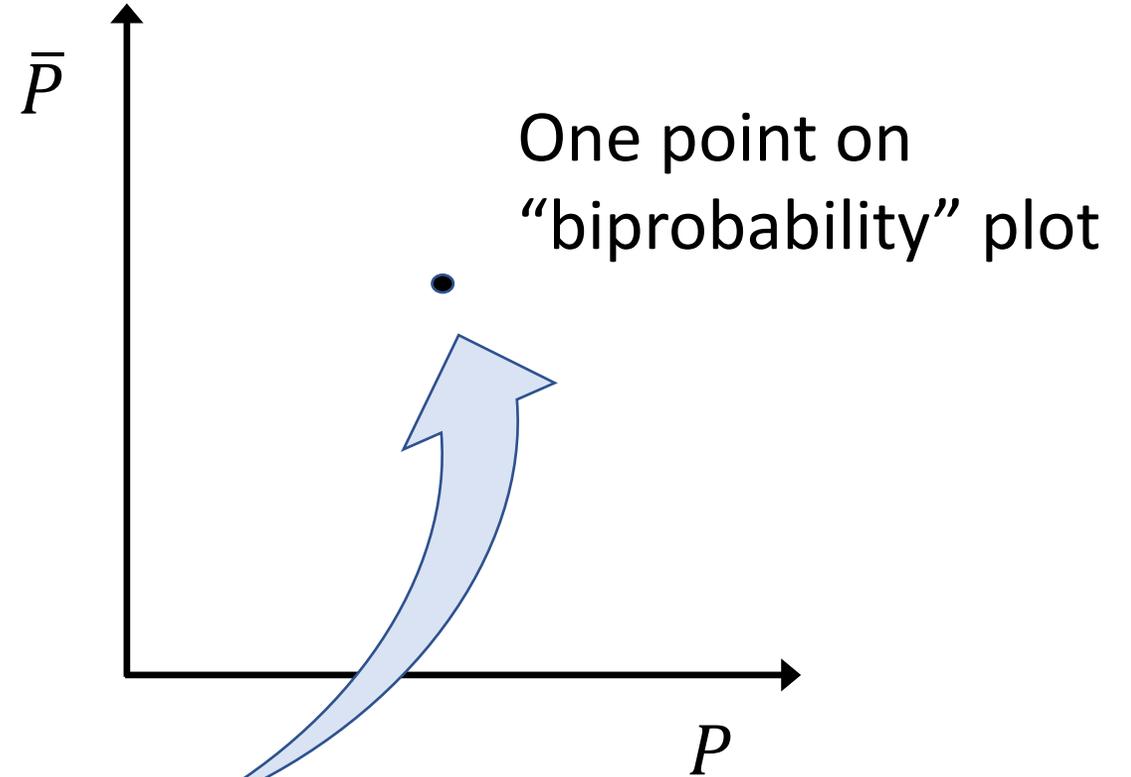

for $\delta_{13} = \pi/3$.

Important, but how to relate possible measurements with effect of individual parameters?

A useful way to visualize parameter degeneracies:

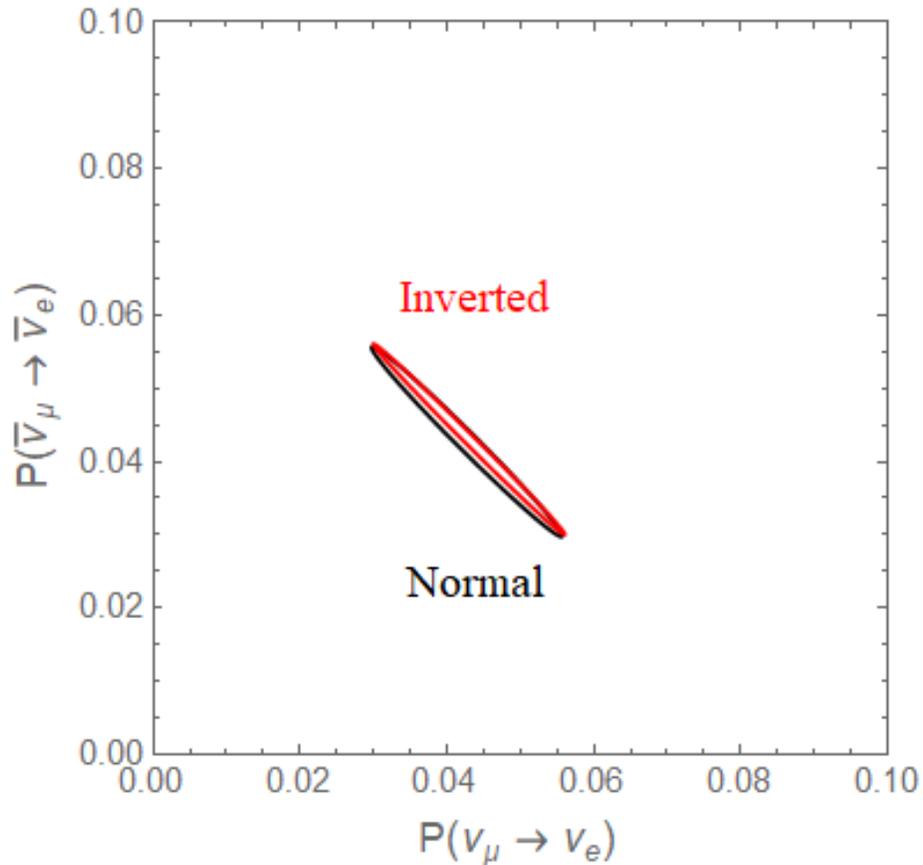

Model parameters
($\theta_{12}, \delta_{13}, \dots$)
and experimental
parameters (L, E, ...)

For example, matter effects lift normal-inverted degeneracy:

[see JHEP 0110 (2001) 001, hep-ph/0108085]

Plot for every value of δ_{13} from 0 to 2π \rightarrow traces out ellipse on biprobability plot:

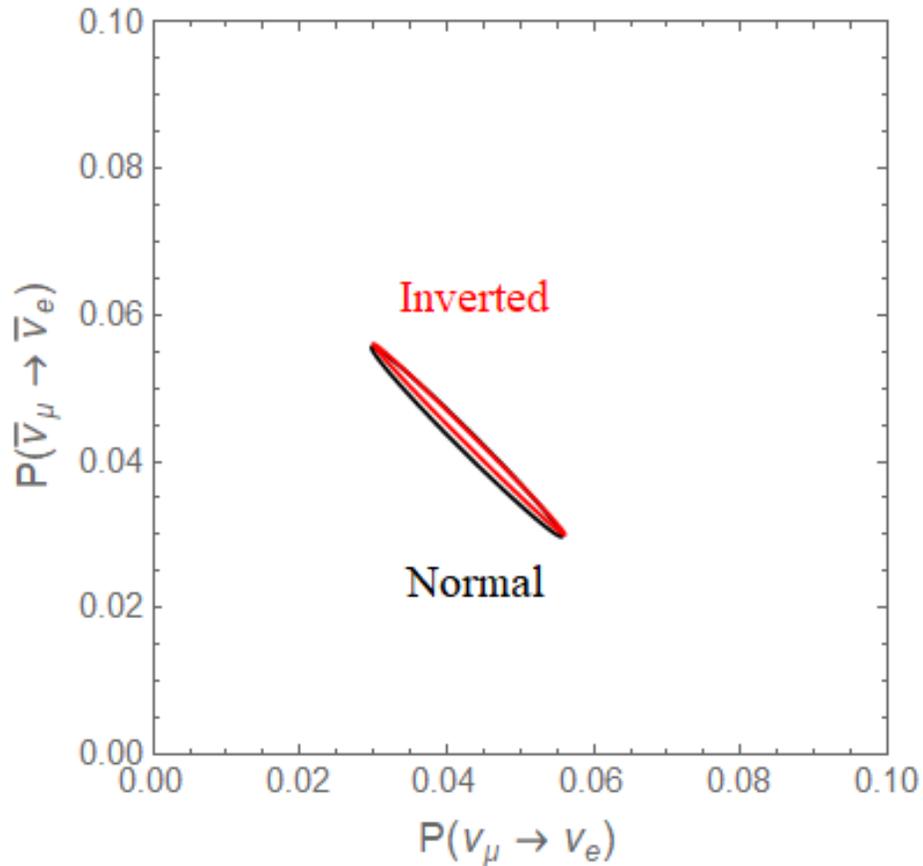

Oscillations in vacuum

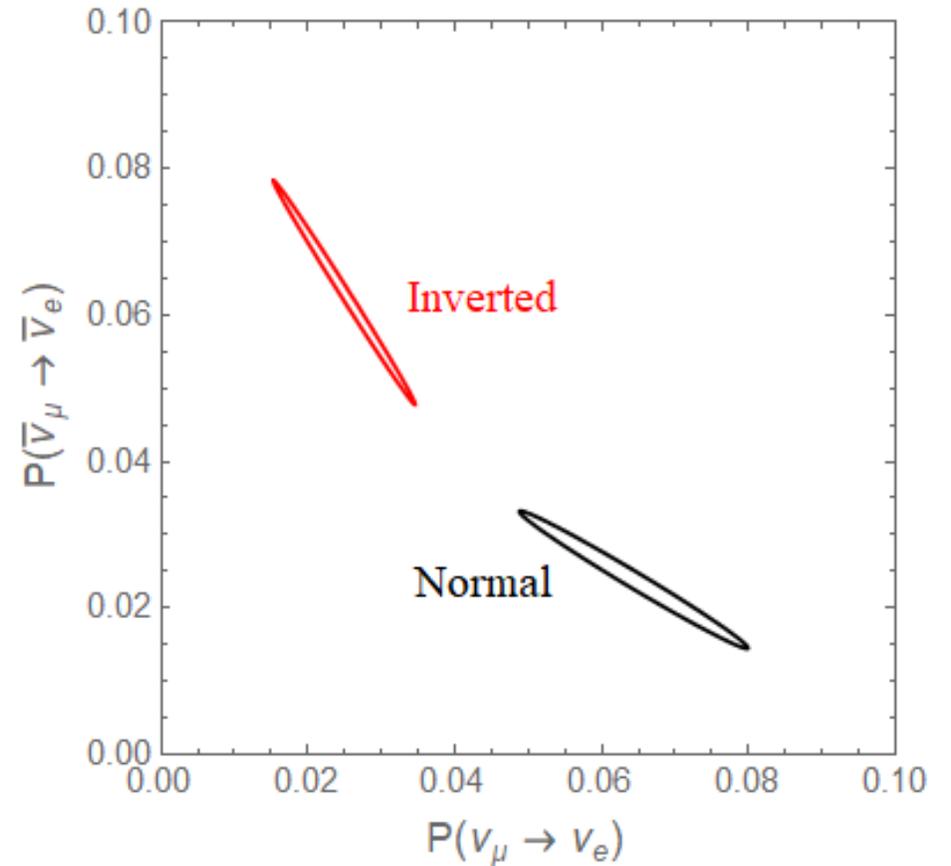

For example, matter effects lift normal-inverted degeneracy:

[see JHEP 0110 (2001) 001, hep-ph/0108085]

Plot for every value of δ_{13} from 0 to 2π \rightarrow traces out ellipse on biprobability plot:

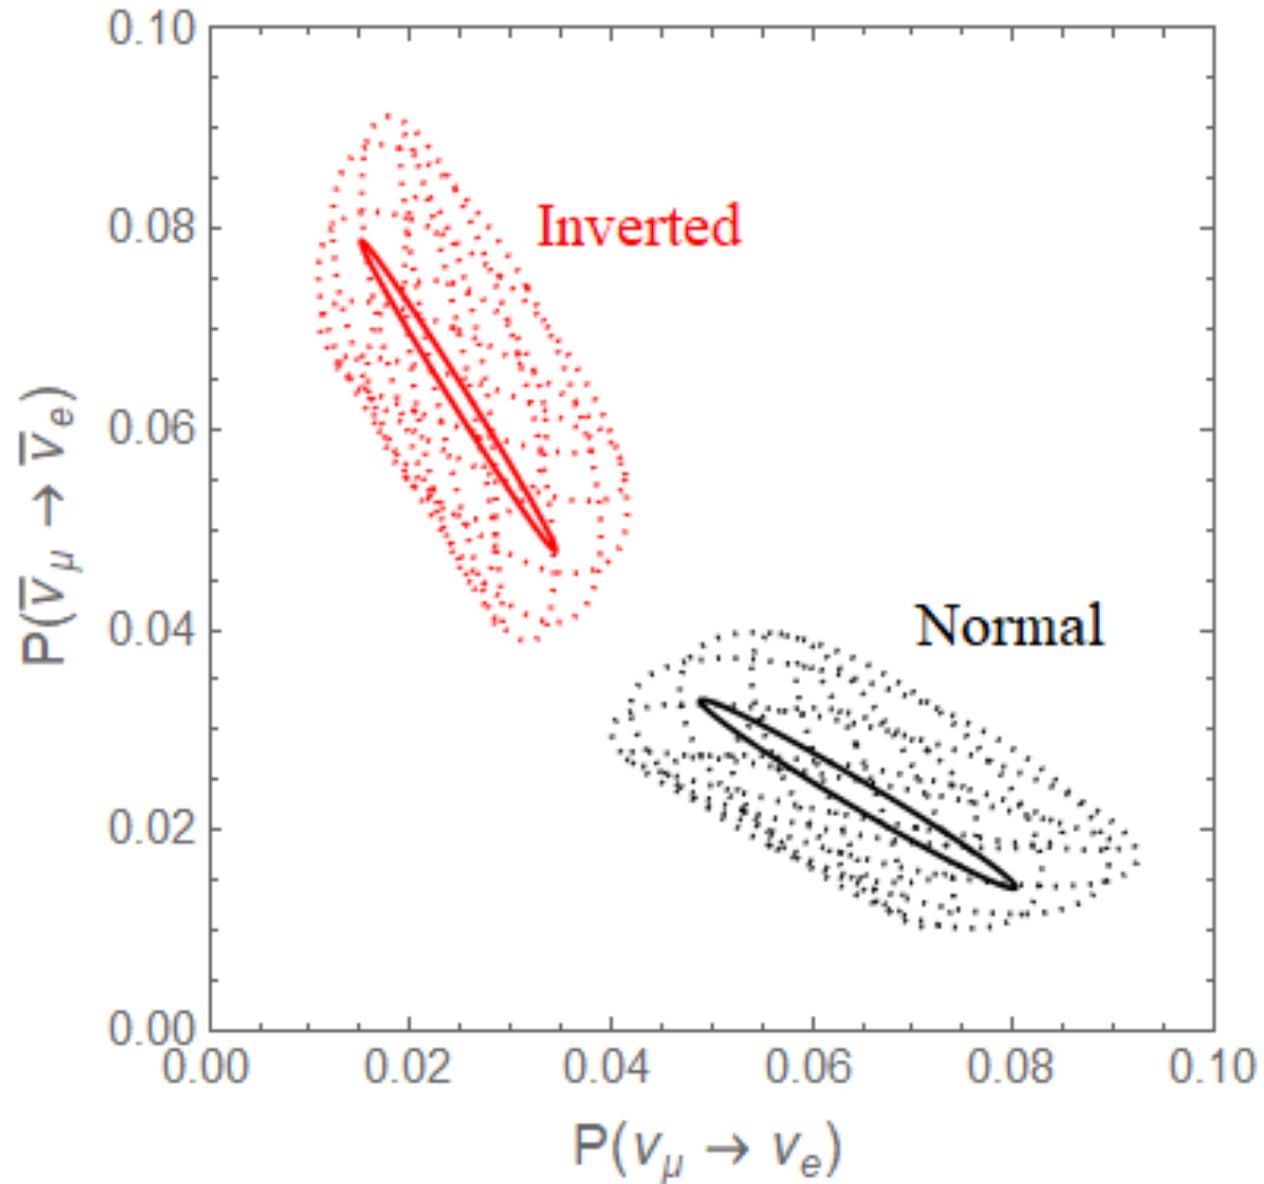

Oscillations in vacuum

Oscillations in matter

Adding NSI significantly complicates the situation:

Oscillation probabilities have form

$$P = (\text{CP-even terms}) + (\text{CP-odd terms})$$

$$\bar{P} = (\text{CP-even terms}) - (\text{CP-odd terms})$$

Therefore, it's natural to choose rotated coordinates

$$P^+ = \frac{1}{\sqrt{2}} (P + \bar{P}) = \sqrt{2} (\text{CP-even terms})$$

$$P^- = \frac{1}{\sqrt{2}} (P - \bar{P}) = \sqrt{2} (\text{CP-odd terms})$$

At $L = 1300$ km with $\Delta_{31} = \Delta m_{31}^2 L / (4E) = \pi/2$ (so $E = 2.5$ GeV), $\rho = 3$ g/cm³:

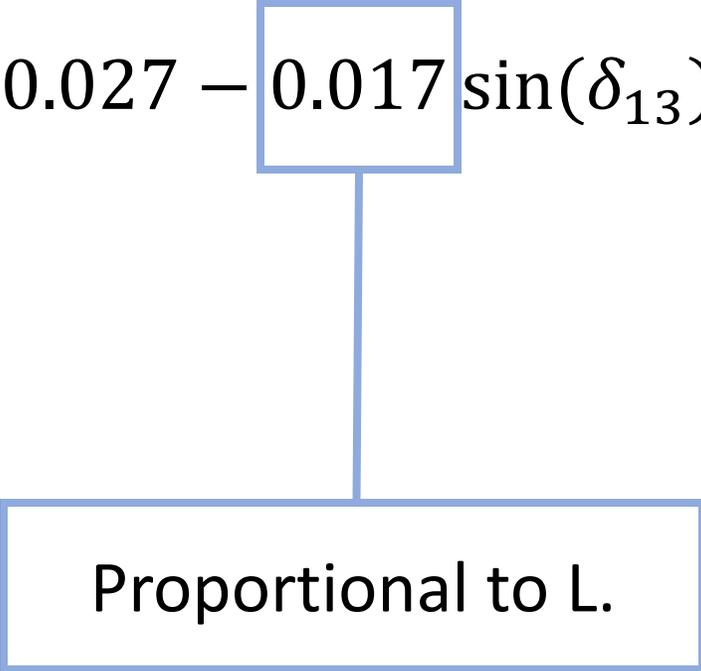

Without NSI, perturbative expressions for oscillation probabilities give:

$$P^+ \approx 0.059, \quad P^- \approx 0.027 - 0.017 \sin(\delta_{13})$$

At $L = 1300$ km with $\Delta_{31} = \Delta m_{31}^2 L / (4E) = \pi/2$ (so $E = 2.5$ GeV), $\rho = 3$ g/cm³:

Without NSI, perturbative expressions for oscillation probabilities give:

$$P^+ \approx 0.059, \quad P^- \approx 0.027 - 0.017 \sin(\delta_{13})$$

Proportional to L.

At $L = 1300$ km with $\Delta_{31} = \Delta m_{31}^2 L / (4E) = \pi/2$ (so $E = 2.5$ GeV), $\rho = 3$ g/cm³:

Without NSI, perturbative expressions for oscillation probabilities give:

$$P^+ \approx 0.059, \quad P^- \approx 0.027 - 0.017 \sin(\delta_{13})$$

With NSI, the same approach gives

$$P^+ \approx 0.059 + 0.21 |\epsilon_{e\mu}| (-\sin(\delta_+) + 0.099 \sin(\delta_{e\mu})),$$
$$P^- \approx 0.027 - 0.017 \sin(\delta_{13}) + 0.22 |\epsilon_{e\mu}| (0.64 \cos(\delta_+) + 0.14 \cos(\delta_{e\mu})),$$

in terms of $\delta_+ = \delta_{13} + \delta_{e\tau}$.

At $L = 1300$ km with $\Delta_{31} = \Delta m_{31}^2 L / (4E) = \pi/2$ (so $E = 2.5$ GeV), $\rho = 3$ g/cm³:

Without NSI, perturbative expressions for oscillation probabilities give:

$$P^+ \approx 0.059, \quad P^- \approx 0.027 - 0.017 \sin(\delta_+)$$

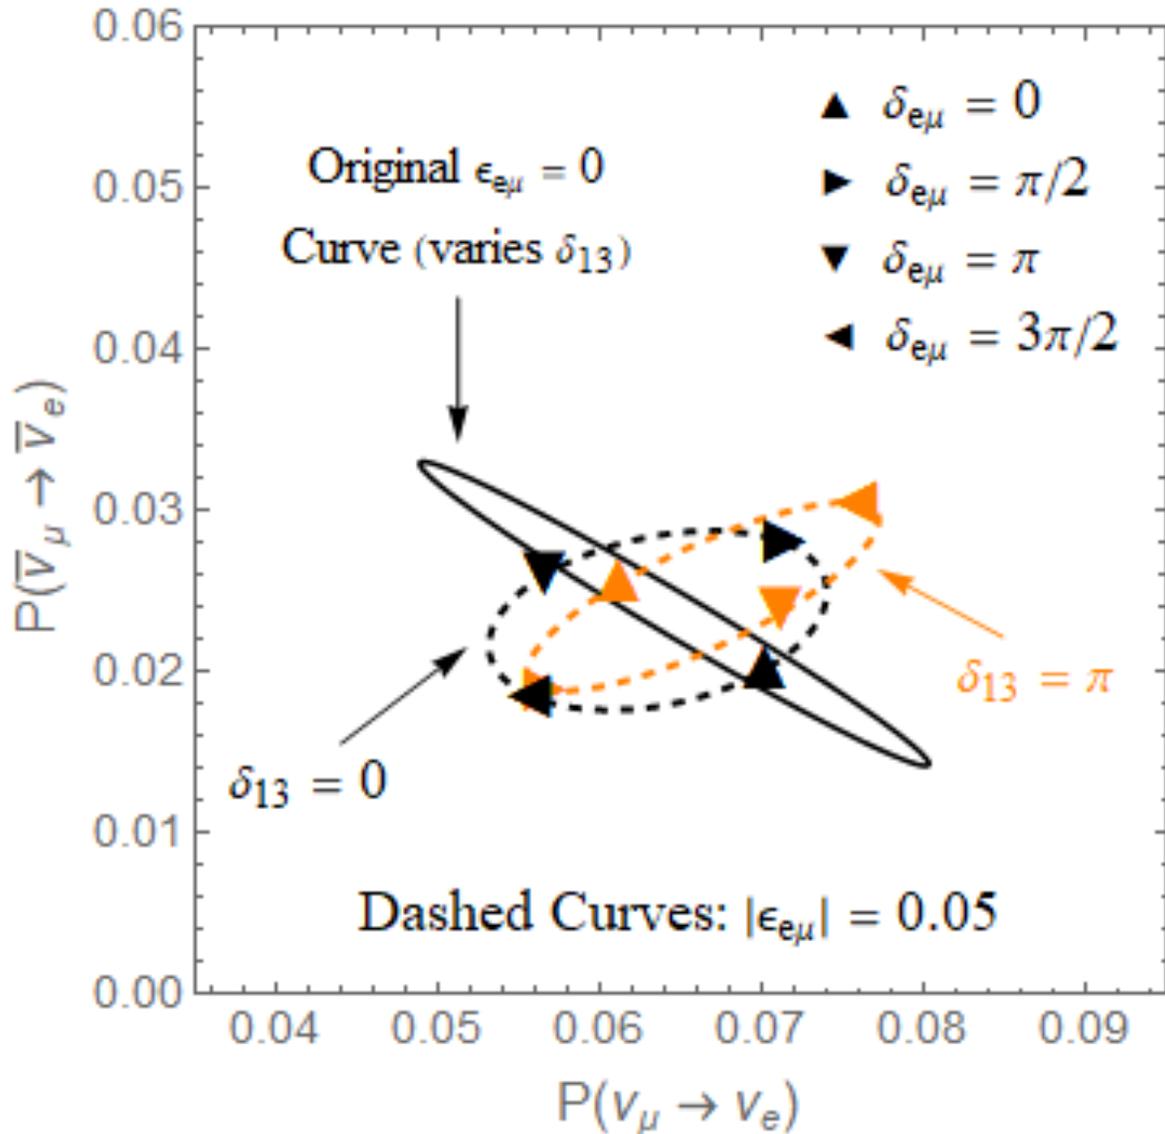

δ_+ dominates
over $\delta_{e\mu}$ here.

With NSI, the same approach gives

$$P^+ \approx 0.059 + 0.21 |\epsilon_{e\mu}| (-\sin(\delta_+) + 0.099 \sin(\delta_{e\mu})),$$
$$P^- \approx 0.027 - 0.017 \sin(\delta_{13}) + 0.22 |\epsilon_{e\mu}| (0.64 \cos(\delta_+) + 0.14 \cos(\delta_{e\mu})),$$

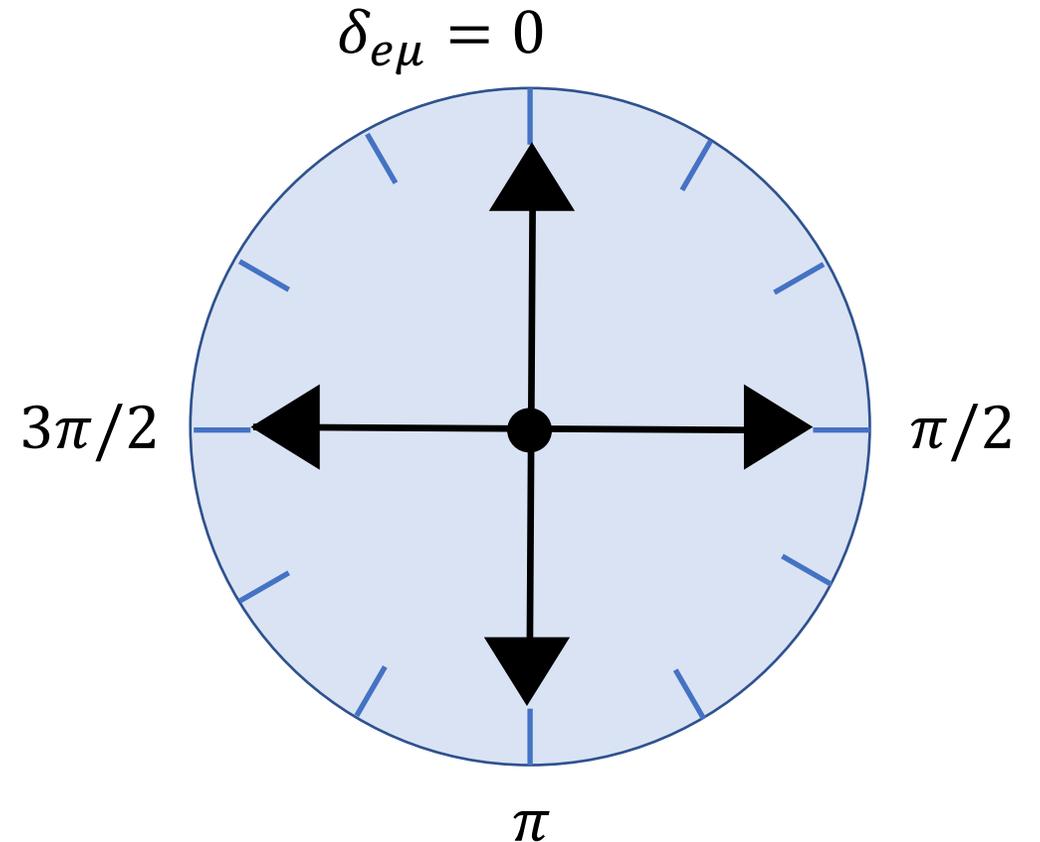

in terms of $\delta_+ = \delta_{13} + \delta_{e\tau}$.

Hold δ_{13} constant, vary $\delta_{e\mu}$:

Dashed curves = constant δ_{13}

Triangles: think of them as “hands on a clock” that go around once per 2π

Look at energies away
from $\Delta_{31} = \pi/2$:

For convenience: Fractional shift in
energy $x \equiv (E - E_0)/E_0$.

Then P^+ gains a term $0.027x \cos(\delta_{13})$
(and some subleading terms).

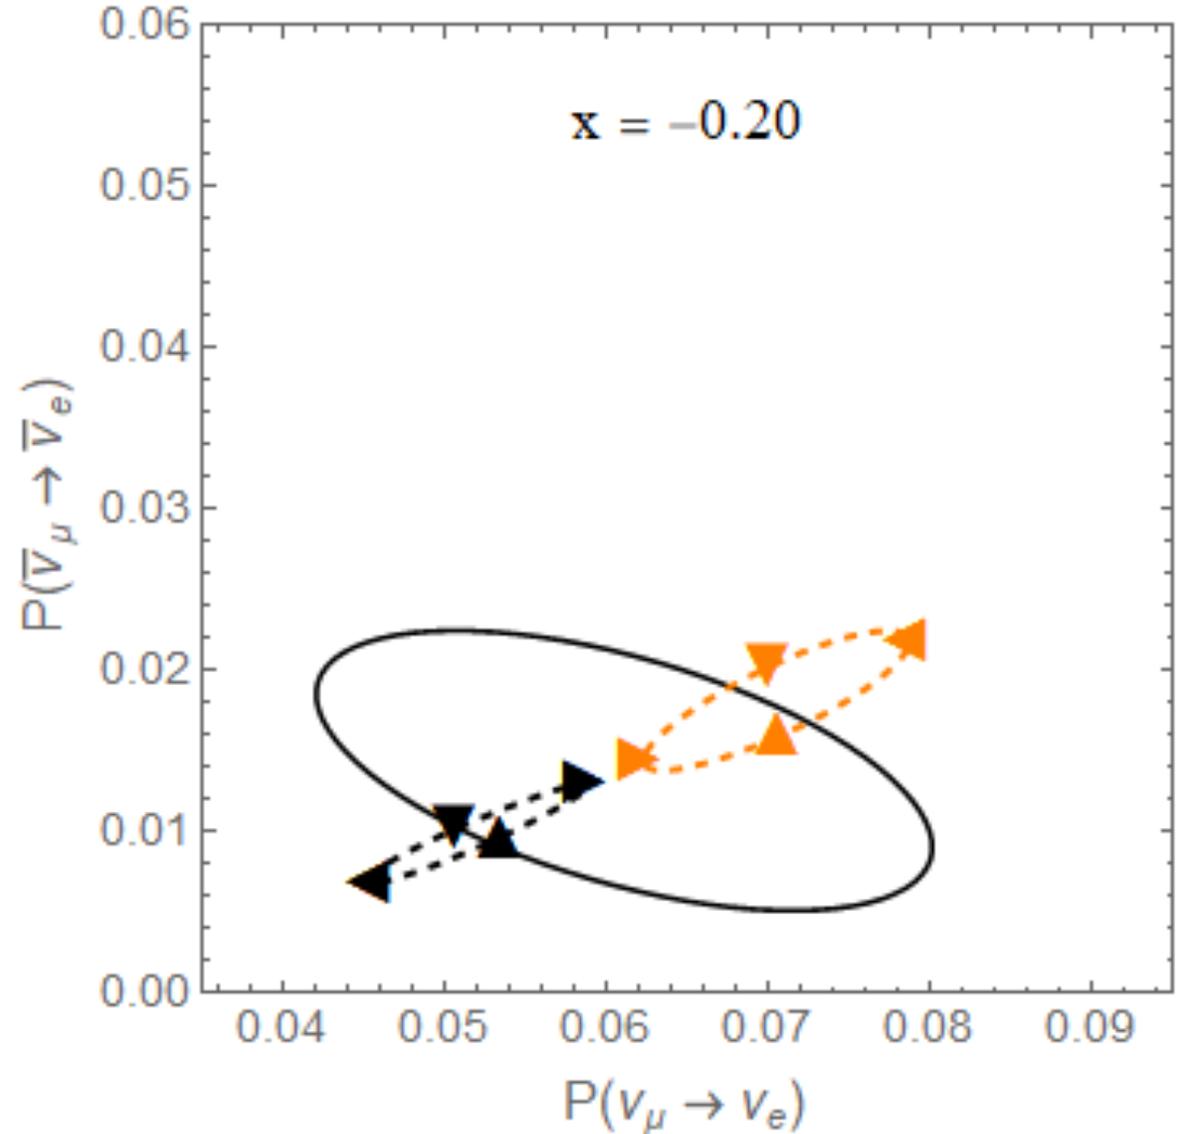

→ Separation in P^+ direction
according to δ_{13} .

Look at energies away
from $\Delta_{31} = \pi/2$:

Then P^+ gains a term $0.027x \cos(\delta_{13})$
(and some subleading terms).

→ Separation in P^+ direction
according to δ_{13} .

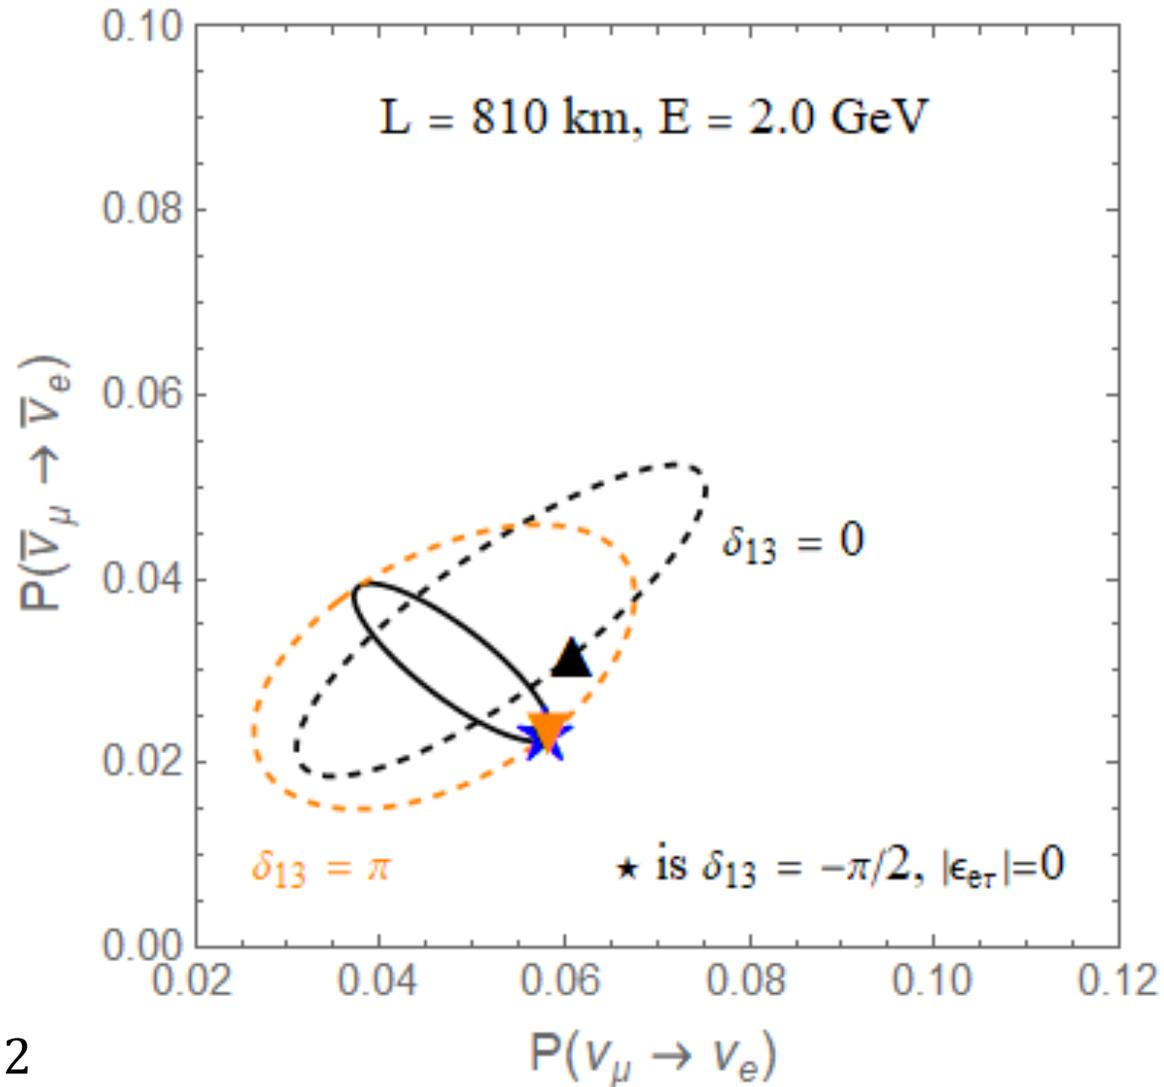

Example: Look at hints for $\delta_{13} \sim -\pi/2$

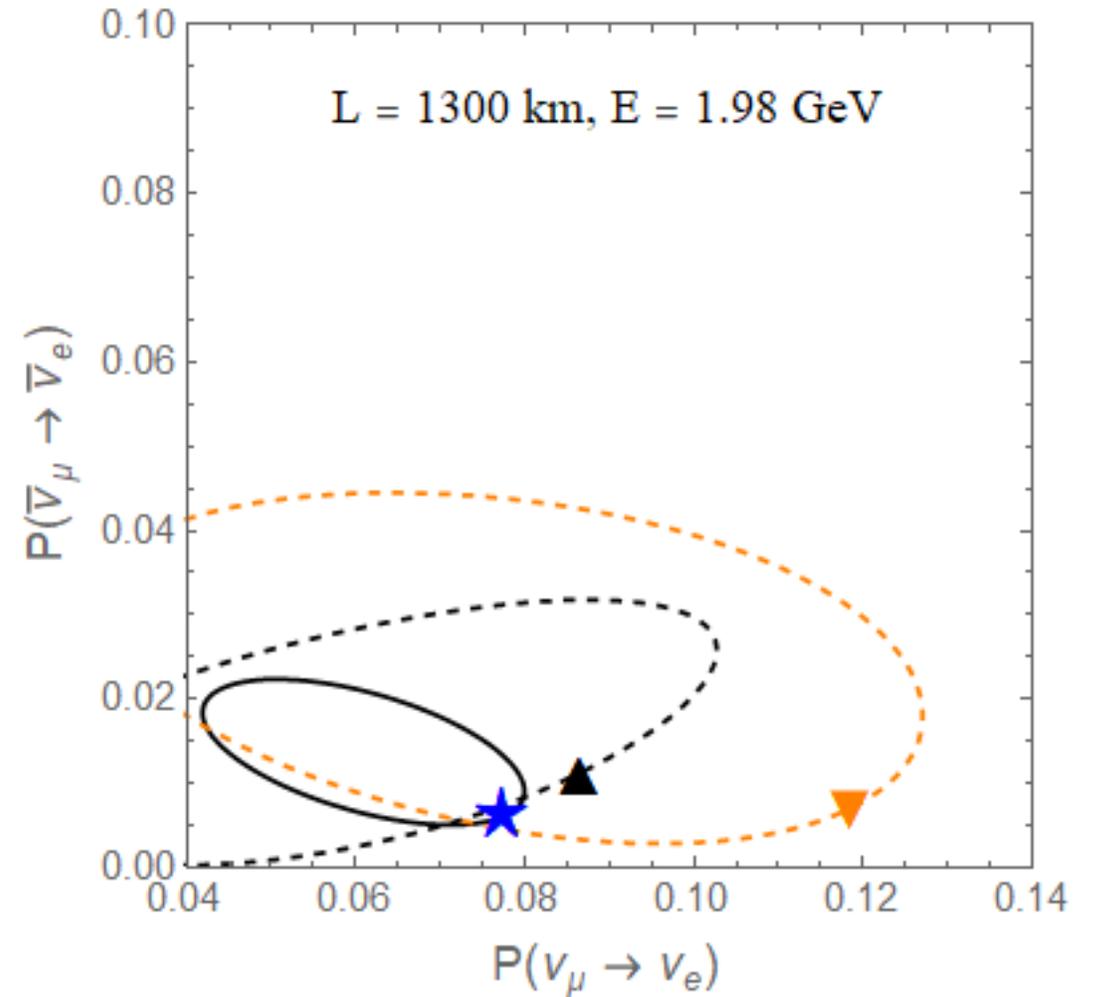

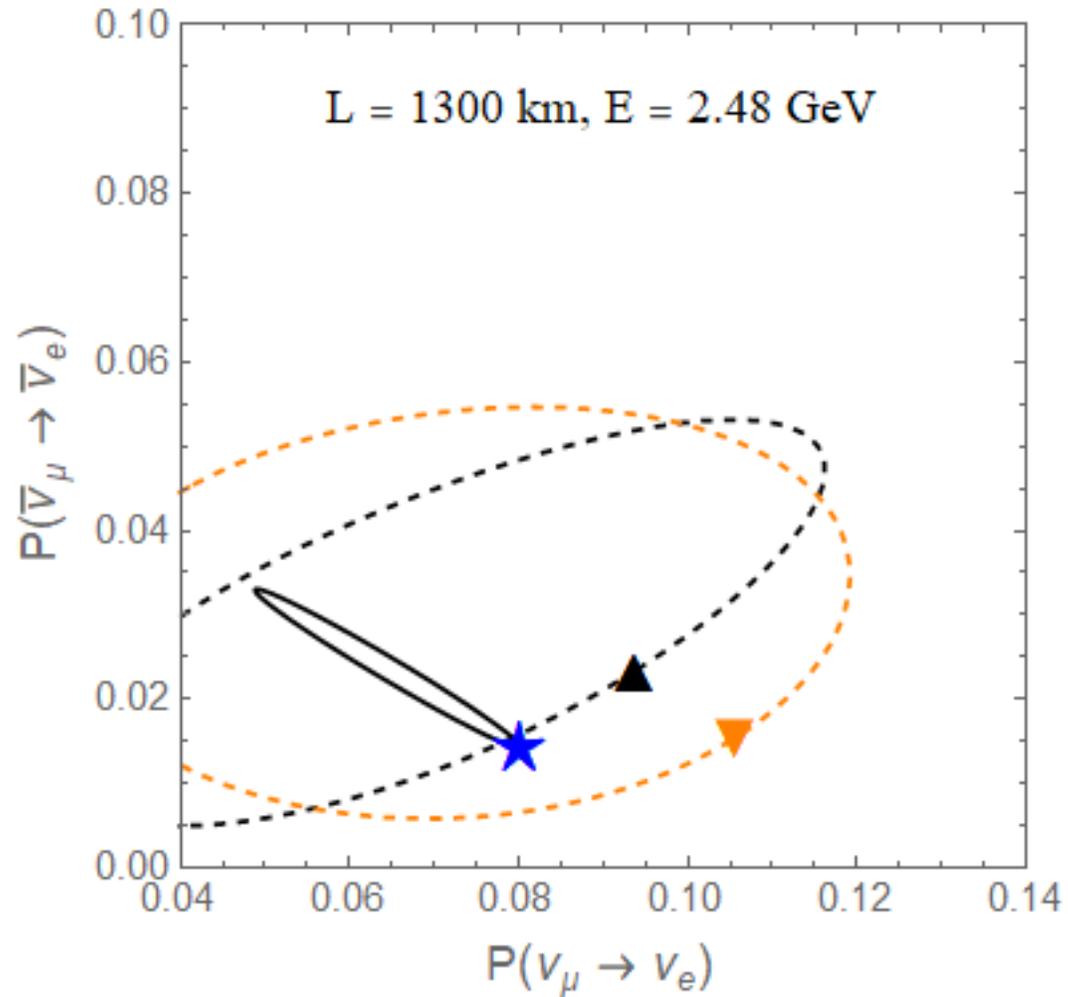

See also e.g. Forero & Huber
PRL 117 (2016)
arXiv:1601.03736

Example: Look at hints for $\delta_{13} \sim -\pi/2$

Dashed curves show $\epsilon_{e\tau} = 0.2$

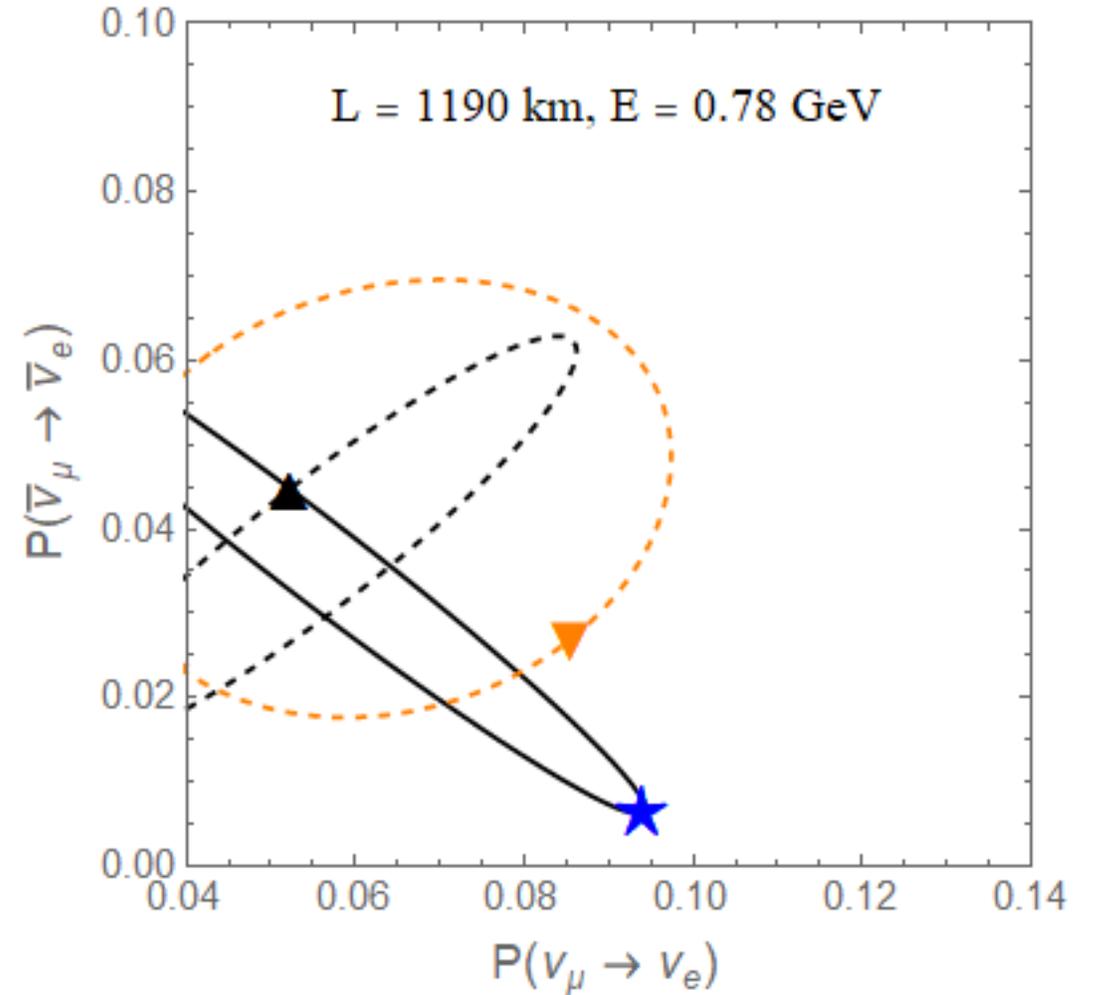

Example: Look at hints for $\delta_{13} \sim -\pi/2$

Further help from $\Delta_{31} = 3\pi/2$
(e.g. T2HKK)

In P^- expression, relative importance
of δ_+ and $\delta_{e\tau}$ switch

→ breaks δ_+ degeneracy along P^-

Take-away points

- At oscillation max ($\Delta_{31} = \pi/2$), probabilities just depend on δ_+ . \rightarrow Degenerate “hidden sector” ellipses of width $\sim 0.1|\epsilon_{e\mu}|$ or $\sim 0.1|\epsilon_{e\tau}|$.
- Away from the peak, there is an effect in the P^+ direction depending on δ_{13}
 \rightarrow Shows specific ways energy spectrum helps lift degeneracy.
- Additional “help” from looking near $\Delta_{31} = 3\pi/2 \rightarrow$ relative importance of δ_+ and δ_{13} switched in P^- expression.
