## **f(Q)-gravity and neutrino physics**

*Tuesday 29 August 2023 21:40 (5 minutes)*

Within the  $f(Q)$ -gravity framework, we perform a phenomenological study of the cosmological observables in light of the degeneracy between neutrinos physics and the modified gravity parameter, and we identify specific patterns which allow us to break such degeneracy. We also provide separately the constraints on the total mass of the neutrinos,  $\Sigma m_\nu$ , and on the effective number of neutrino species,  $N_{\text{eff}}$ , using cosmic microwave background (CMB), baryon acoustic oscillation (BAO), redshift space distortion (RSD), supernovae (SNIa), galaxy clustering (GC) and weak gravitational lensing (WL) measurements. We find that all combinations of data we consider prefer a stronger gravitational interaction than  $\Lambda$ CDM. Finally, we consider the chi-square and deviance information criterion statistics and find the  $f(Q) + \Sigma m_\nu$  model to be statistically supported by data over the standard scenario. On the contrary,  $f(Q) + N_{\text{eff}}$  is supported by CMB+BAO+RSD+SNIa but a moderate evidence against it is found with GC and WL data.
