## Cosmic Neutrinos from a Blazar (12'+3')

*Tuesday 16 October 2018 11:15 (15 minutes)*

This summer IceCube announced the first evidence of a cosmic source of high-energy neutrinos. A rare, high-energy neutrino event detected on 2017 Sept. 22 was reported by IceCube in a public alert that led to extensive follow-up observations across the electromagnetic spectrum. A tantalizing association was found with a blazar, an active galaxy where one of the jets from the central black hole is pointed in our direction. Subsequent analysis of archival IceCube data revealed further evidence that the blazar had a previous episode of neutrino emission. These results may for the first time identify a long-sought accelerator of high-energy cosmic rays.
