# Astrophysical distribution of DM & direct detection implications

#### Nassim Bozorgnia

GRAPPA Center of Excellence University of Amsterdam

#### Dark Matter halo

# How is Dark Matter (DM) distributed in the Sun's neighborhood?

#### Dark Matter halo

# How is Dark Matter (DM) distributed in the Sun's neighborhood?

Uncertainties in the local DM distribution —> large uncertainties in the interpretation of direct detection data.

#### Dark Matter halo

# How is Dark Matter (DM) distributed in the Sun's neighborhood?

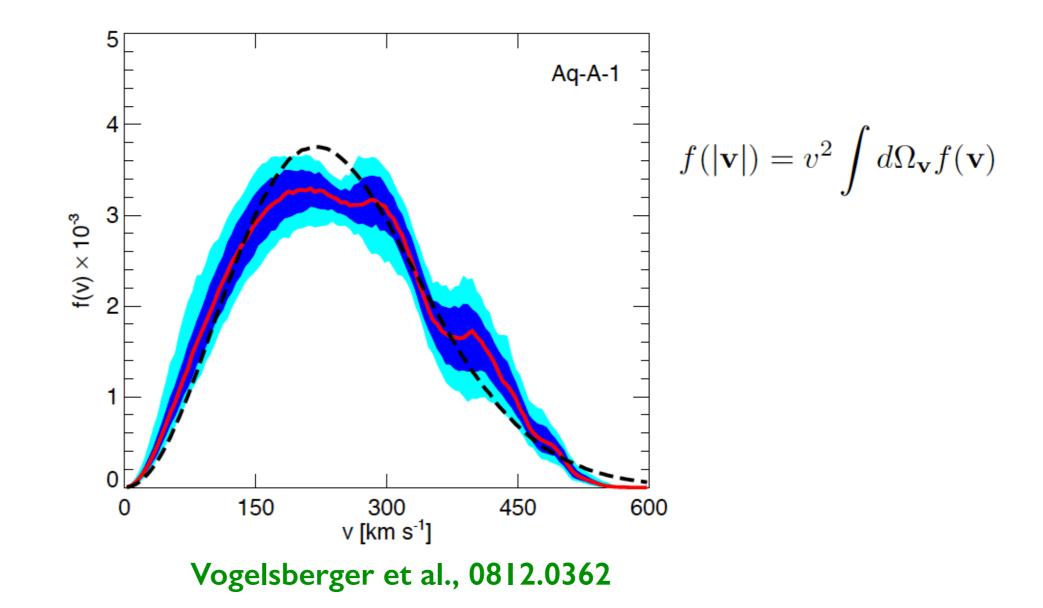

Uncertainties in the local DM distribution —> large uncertainties in the interpretation of direct detection data.

- Standard Halo model (SHM): isothermal sphere with an isotropic Maxwell-Boltzmann velocity distribution with a peak speed equal to the local circular speed (~220 km/s).
- What can we learn from numerical simulations of galaxy formation about the local DM velocity distribution?

### Dark Matter only simulations

 DM speed distributions from cosmological N-body simulations without baryons, deviate substantially from a Maxwellian.

• Significant systematic uncertainty since the impact of baryons neglected.

## Hydrodynamical simulations

 Each hydrodynamical (DM + baryons) simulation adopts a different galaxy formation model, spatial resolution, DM particle mass.

 Large variation in DM speed distributions between the results of different simulations.

## Hydrodynamical simulations

 Each hydrodynamical (DM + baryons) simulation adopts a different galaxy formation model, spatial resolution, DM particle mass.

 Large variation in DM speed distributions between the results of different simulations.

#### EAGLE and APOSTLE

 We use the EAGLE and APOSTLE hydrodynamic simulations.
 Calibrated to reproduce the observed distribution of stellar masses and sizes of low-redshift galaxies.

# Identifying Milky Way analogues

 Identify MW-like galaxies by taking into account observational constraints on the MW, in addition to the mass constraint: rotation curves [locco, Pato, Bertone, 1502.03821], total stellar mass.

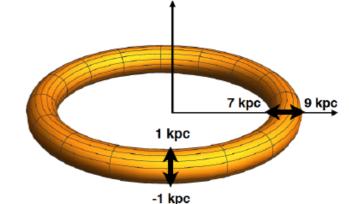

### Local Dark Matter distribution

• To find the DM distribution at the position of the Sun, consider a torus aligned with the stellar disc.

Local DM density:

$$\rho_{\chi}$$
 = 0.41 - 0.73 GeV/cm<sup>3</sup>

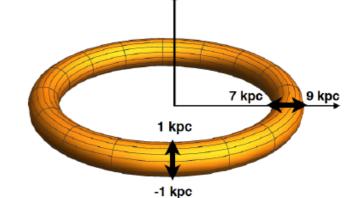

### Local Dark Matter distribution

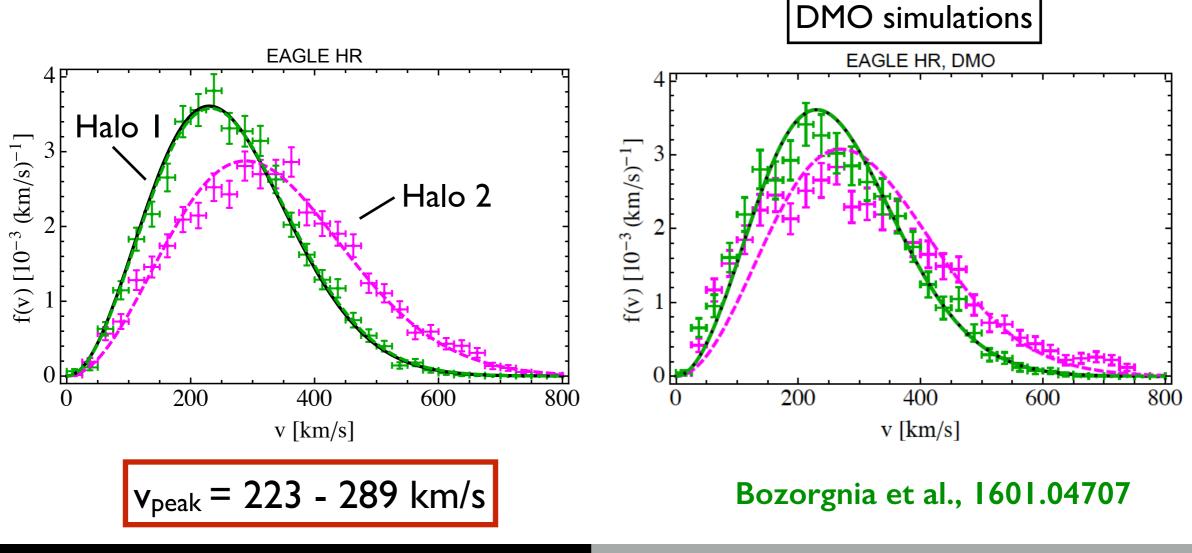

• To find the DM distribution at the position of the Sun, consider a torus aligned with the stellar disc.

Local DM density:

$$\rho_{\rm X}$$
 = 0.41 - 0.73 GeV/cm<sup>3</sup>

Local DM speed distribution:

Nassim Bozorgnia

TeVPA 2017, Columbus, 10 August 2017

### Local Dark Matter distribution

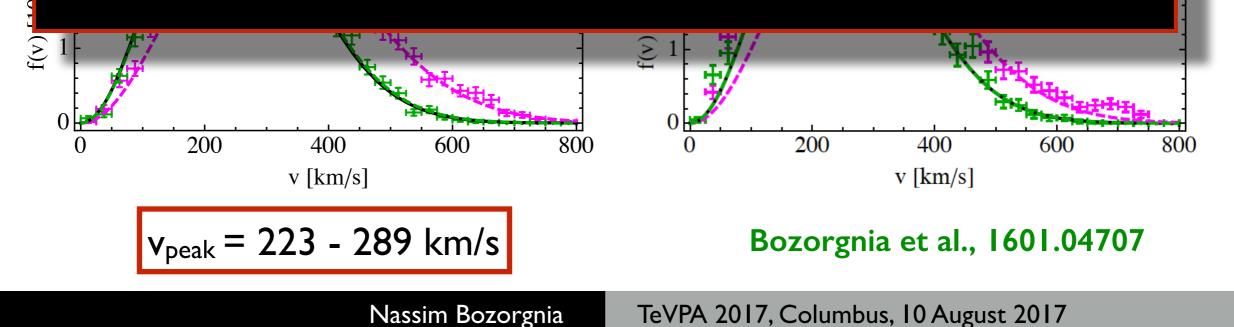

7 kpc

1 kpc

9 kpc

• To find the DM distribution at the position of the Sun, consider a torus aligned with the stellar disc.

- Maxwellian distribution with a free peak provides a better fit to haloes in the hydrodynamical simulations compared to their DMO counterparts.
- Common trend: in most hydrodynamical simulations, baryons appear to make the local DM speed distribution more Maxwellian.

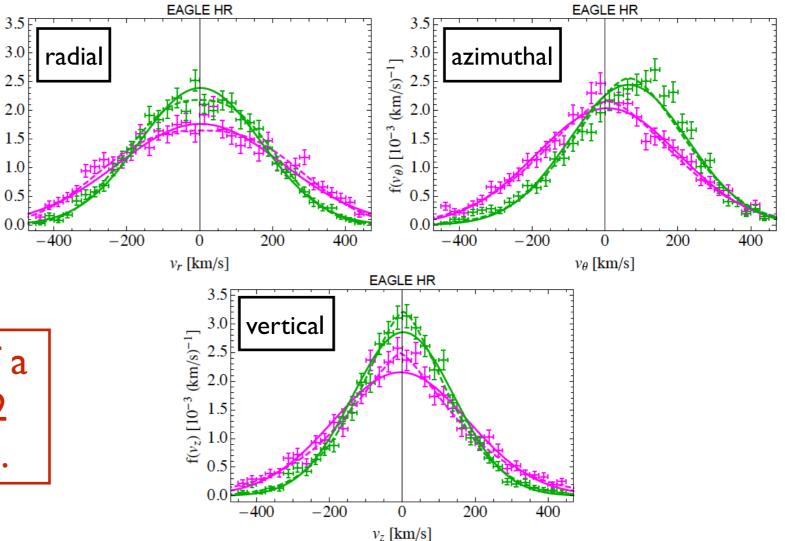

#### How common are dark disks?

 $f(v_r) [10^{-3} (km/s)^{-1}]$ 

 Only two haloes have a rotating DM component in the disc with mean velocity comparable to that of the stars.

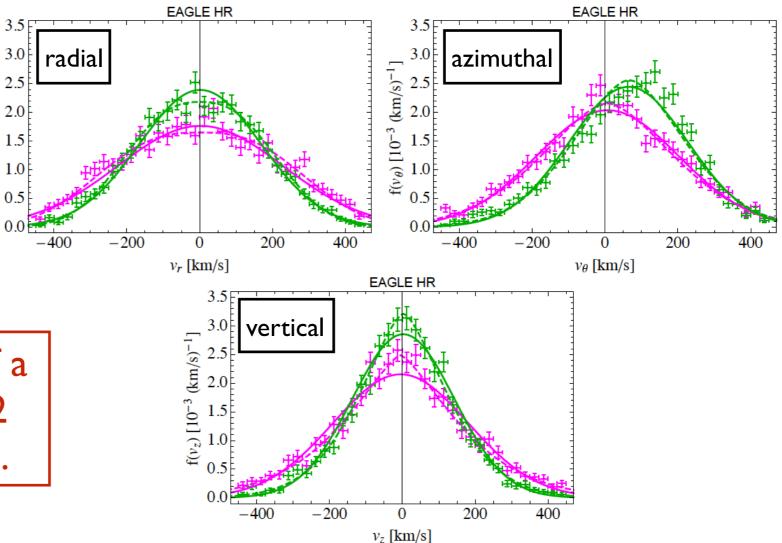

Hint for the existence of a co-rotating dark disk in 2 out of 14 MW analogues.

### How common are dark disks?

 Only two haloes have a rotating DM component in the disc with mean velocity comparable to that of the stars.

Hint for the existence of a co-rotating dark disk in 2 out of 14 MW analogues.

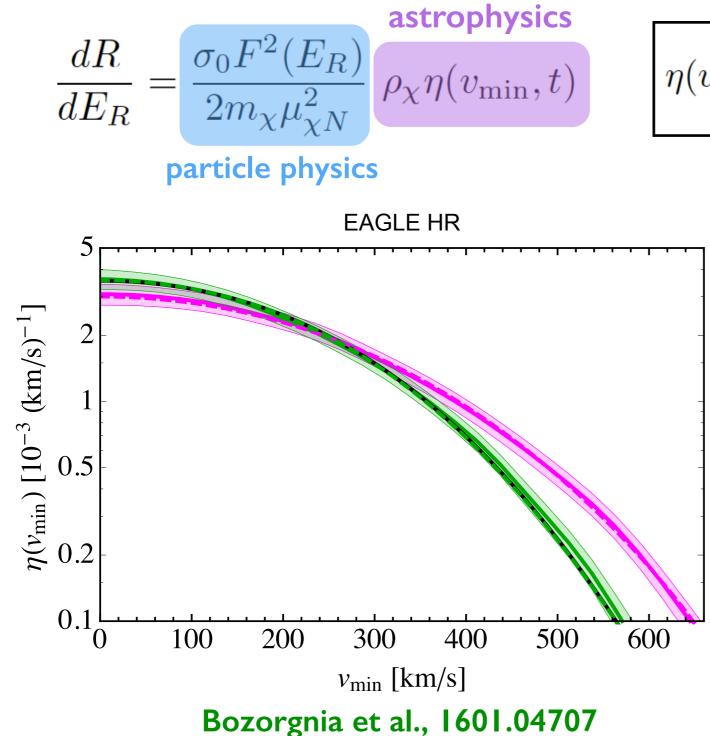

• Sizable dark disks also rare in other hydro simulations:

 $(v_r) [10^{-3} (km/s)^{-1}]$ 

 They only appear in simulations where a large satellite merged with the MW in the recent past, which is robustly excluded from MW kinematical data.

## The halo integral

• For standard spin-independent and spin-dependent interactions:

$$\eta(v_{\min}, t) \equiv \int_{v > v_{\min}} d^3 v \ \frac{f_{\det}(\mathbf{v}, \mathbf{t})}{v}$$

Halo integrals for the best fit Maxwellian velocity distribution (peak speed 223 - 289 km/s) fall within the I σ uncertainty band of the halo integrals of the simulated haloes.

# The halo integral

- For standard spin-independent and spin-dependent interactions:
  - This conclusion also holds for a very general set of nonstandard DM-nucleus interactions.
  - Common trend: halo integrals and hence direct detection event rates obtained from a Maxwellian velocity distribution with a free peak are similar to those obtained directly from the simulated haloes.

#### Implications for direct detection

Fix local  $\rho_{\chi}$ =0.3 GeV cm<sup>-3</sup>

- Difference in the local DM density —> overall difference with the SHM.
- Variation in the peak of the DM speed distribution —> shift in the low mass region.

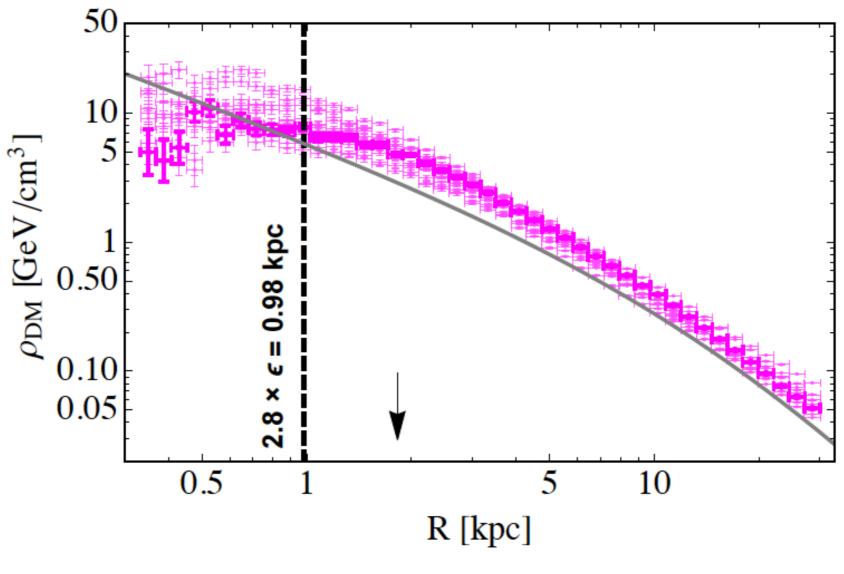

# Summary

- To make precise quantitative predictions for the DM distribution from simulations —> Identify MW analogues by taking into account observational constraints on the MW.
  - Local DM density agrees with local and global estimates.
  - Halo integrals of MW analogues match well those obtained from best fit Maxwellian velocity distributions.
- A Maxwellian velocity distribution with peak speed constrained by hydrodynamical simulations, and independent from the local circular speed, could be used for the analysis of direct detection data.

#### Dark Matter density profiles

• Spherically averaged DM density profiles of the MW analogues:

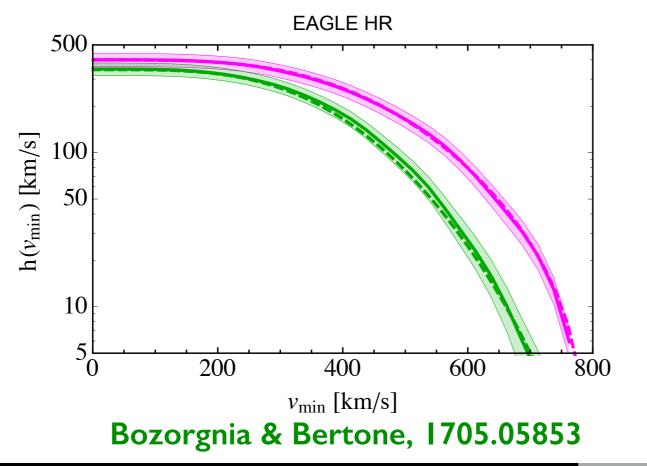

Bozorgnia et al., 1601.04707

#### Non-standard interactions

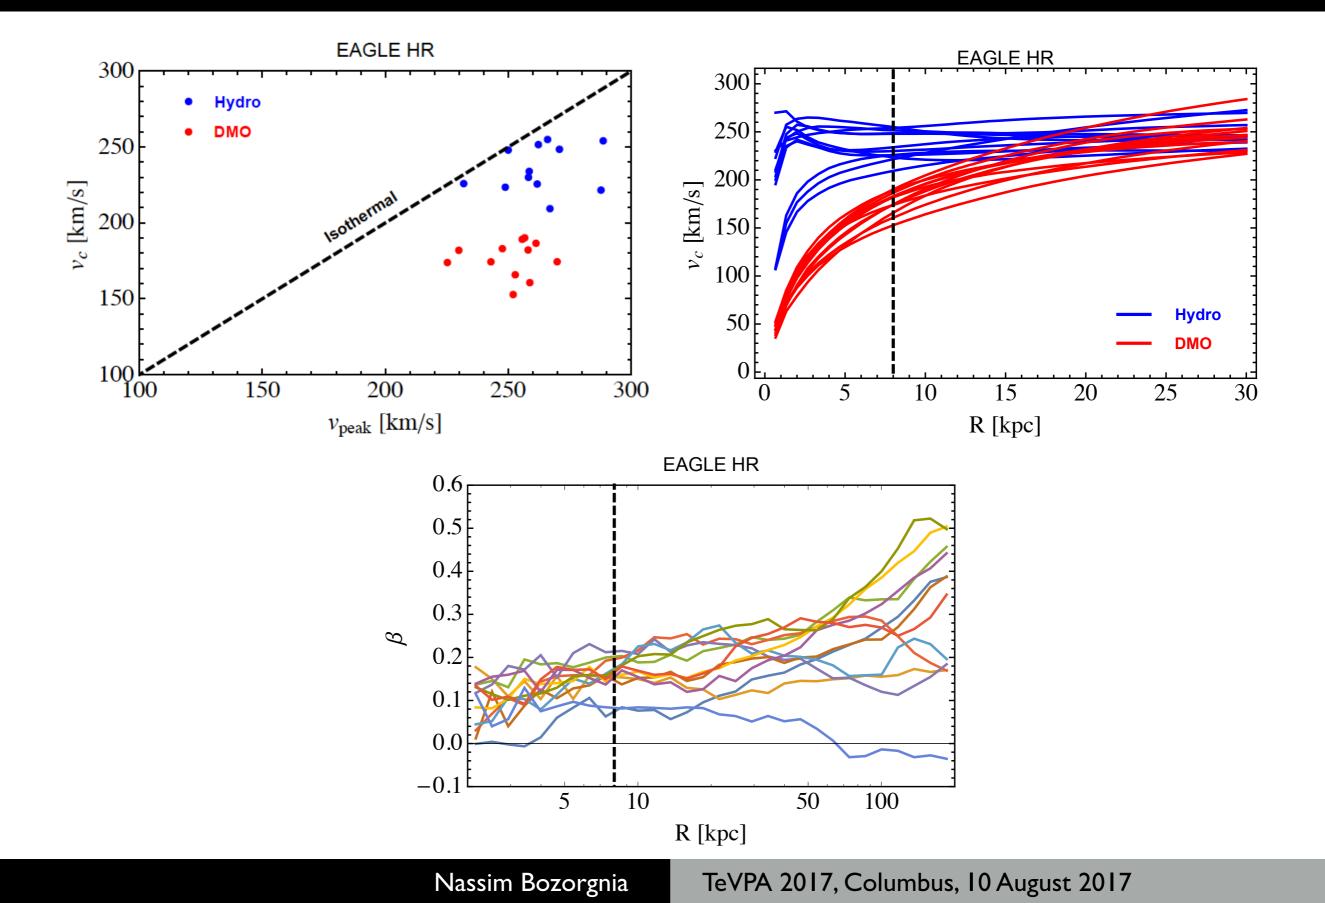

• For a very general set of non-relativistic effective operators: Kahlhoefer & Wild, 1607.04418

$$\frac{d\sigma_{\chi N}}{dE_R} = \frac{d\sigma_1}{dE_R} \frac{1}{v^2} + \frac{d\sigma_2}{dE_R}$$
$$\eta(v_{\min}, t) \qquad h(v_{\min}, t) = \int_{v > v_{\min}} d^3v \ v \ f_{det}(\mathbf{v}, t)$$

• Best fit Maxwellian  $h(v_{\min})$ falls within the  $I \sigma$ uncertainty band of the  $h(v_{\min})$  of the simulated haloes.

#### Departure from isothermal

#### Parameters of the simulations

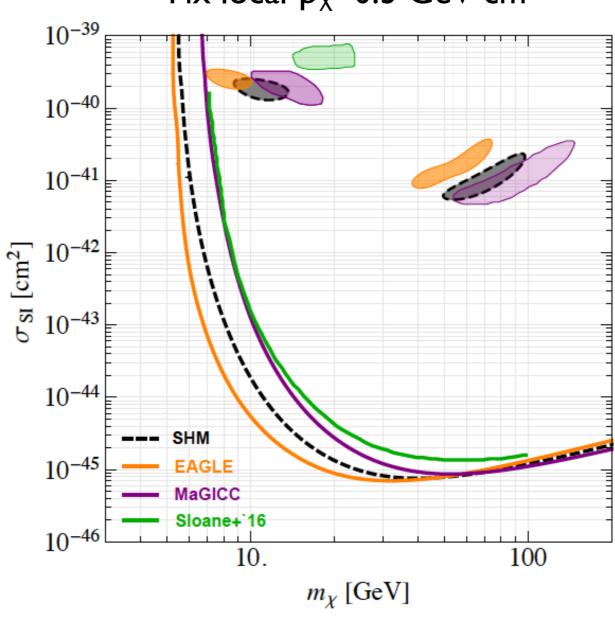

Simulation	code	$N_{\rm DM}$	$m_{ m g}~[{ m M}_{\odot}]$	$m_{\rm DM}~[{\rm M}_\odot]$	$\epsilon \; [pc]$
Ling et al.	RAMSES	2662	_	$7.46\times 10^5$	200

#### Implications for direct detection

#### Comparison to other hydrodynamical simulations:

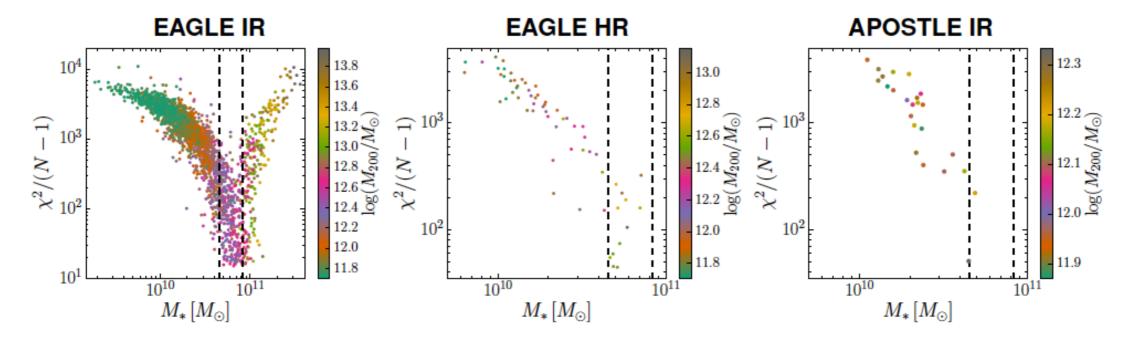

#### Fix local $\rho_{\rm X}$ =0.3 GeV cm<sup>-3</sup>

Bozorgnia & Bertone, 1705.05853

#### Observations vs. simulations

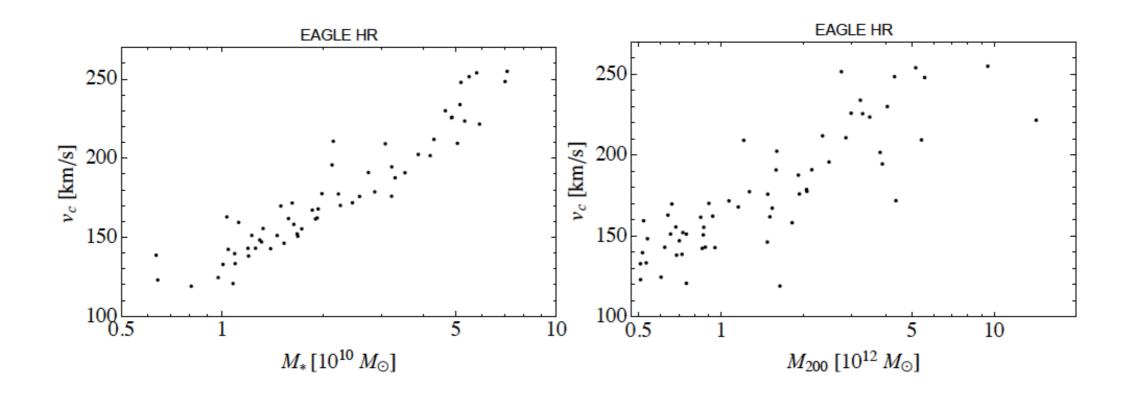

#### Goodness of fit to the observed data:

N = 2687 is the total number of observational data points used.

- Minimum of the reduced  $\chi^2$  occurs within the  $3\sigma$  measured range of the MW total stellar mass.  $\Rightarrow$  haloes with correct MW stellar mass have rotation curves which match well the observations.
- We focus only on the selected EAGLE HR and APOSTLE IR haloes due to higher resolution => total of 14 MW analogues.

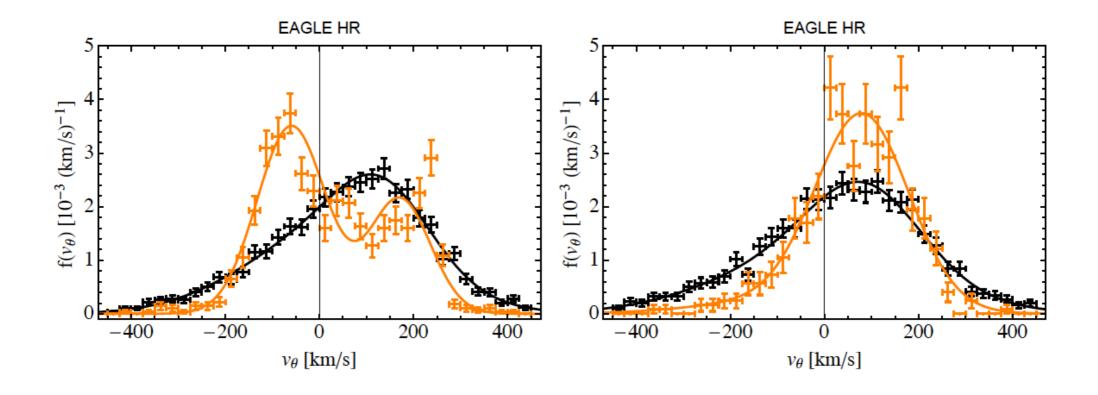

# Selection criteria for MW analogues

- M<sub>\*</sub> strongly correlated with v<sub>c</sub> at 8 kpc, while the correlation of M<sub>200</sub> with v<sub>c</sub> is weaker.
- $M_{\star}(R < 8 \text{ kpc}) = (0.5 0.9)M_{\star}$ .
- $M_{\rm tot}(R < 8 \, \rm kpc) = (0.01 0.1) M_{200}$ .
- Over the small halo mass range probed, little correlation between M<sub>DM</sub>(R < 8 kpc) and M<sub>200</sub>.

### Searching for dark disks

#### DM and stellar velocity distributions:

- Fit with a double Gaussian. Difference in the mean speed of second Gaussian between DM and stars is 35 km/s in the left, and 7 km/s in the right panel.
- Fraction of second Gaussian is 32% in the left panel and 43% in the right panel.

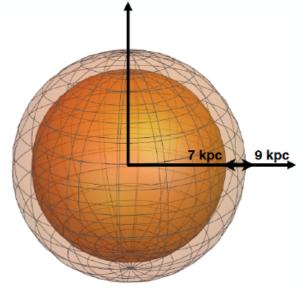

### Searching for dark disks

Is there an enhancement of the local DM density in the **Galactic disc** compared to the **halo**?

Compare the the average \(\rho\_{DM}\) in the torus with the value in a spherical shell at 7 < R < 9 kpc.</p>

 $ho_{\rm DM}^{\rm torus}$  is larger than  $ho_{\rm DM}^{\rm shell}$  by:

2 – 27% for 10 haloes, greater than 10% for 5 haloes, and greater than 20% for only two haloes.

The increase in the DM density in the disc could be due to the DM halo contraction as a result of dissipational baryonic processes.

### Halo shapes

- ► To study the shape of the inner (R < 8 kpc) DM haloes, we calculate the inertia tensor of DM particles within 5 and 8 kpc.</p>
  ⇒ ellipsoid with three axes of length a ≥ b ≥ c.
- Calculate the sphericity: s = c/a.
  - s = 1: perfect sphere. s < 1: increasing deviation from sphericity.
  - At 5 kpc, s = [0.85, 0.95]. At 8 kpc, s lower by less than 10%.
  - Due to dissipational baryonic processes, DM sphericity systematically higher in the hydrodynamic simulations compared to DMO haloes in which s = [0.75, 0.85].

### Halo shapes

Describe a deviation from sphericity by the triaxiality parameter:

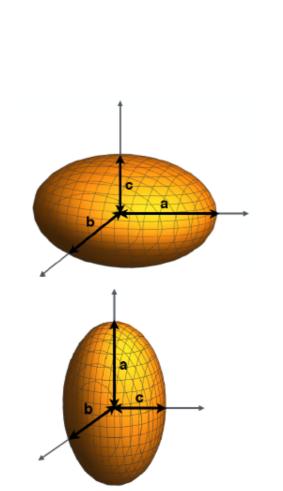

$$T=\frac{a^2-b^2}{a^2-c^2}$$

0

. 0

• Oblate systems,  $a \approx b \gg c \Rightarrow T \approx 0$ .

▶ Prolate systems,  $a \gg b \approx c \Rightarrow T \approx 1$ .

In the hydro case, since inner haloes are very close to spherical, deviation towards either oblate or prolate is small. DMO counterparts have a preference for *prolate* inner haloes.
