

Finale of a Quartet: Hints on Supernova Formation

Xiao Fang

CCAPP, Department of Physics

Advisors: *Todd Thompson, Christopher Hirata*

Type *Ia* Supernovae

©High-Z Supernova Search Team/HST/NASA

We Know:

- Standard candles
- Thermonuclear explosion of WD matter

We don't know how they form

How Do Type *Ia* Supernovae Form?

WD+WD?

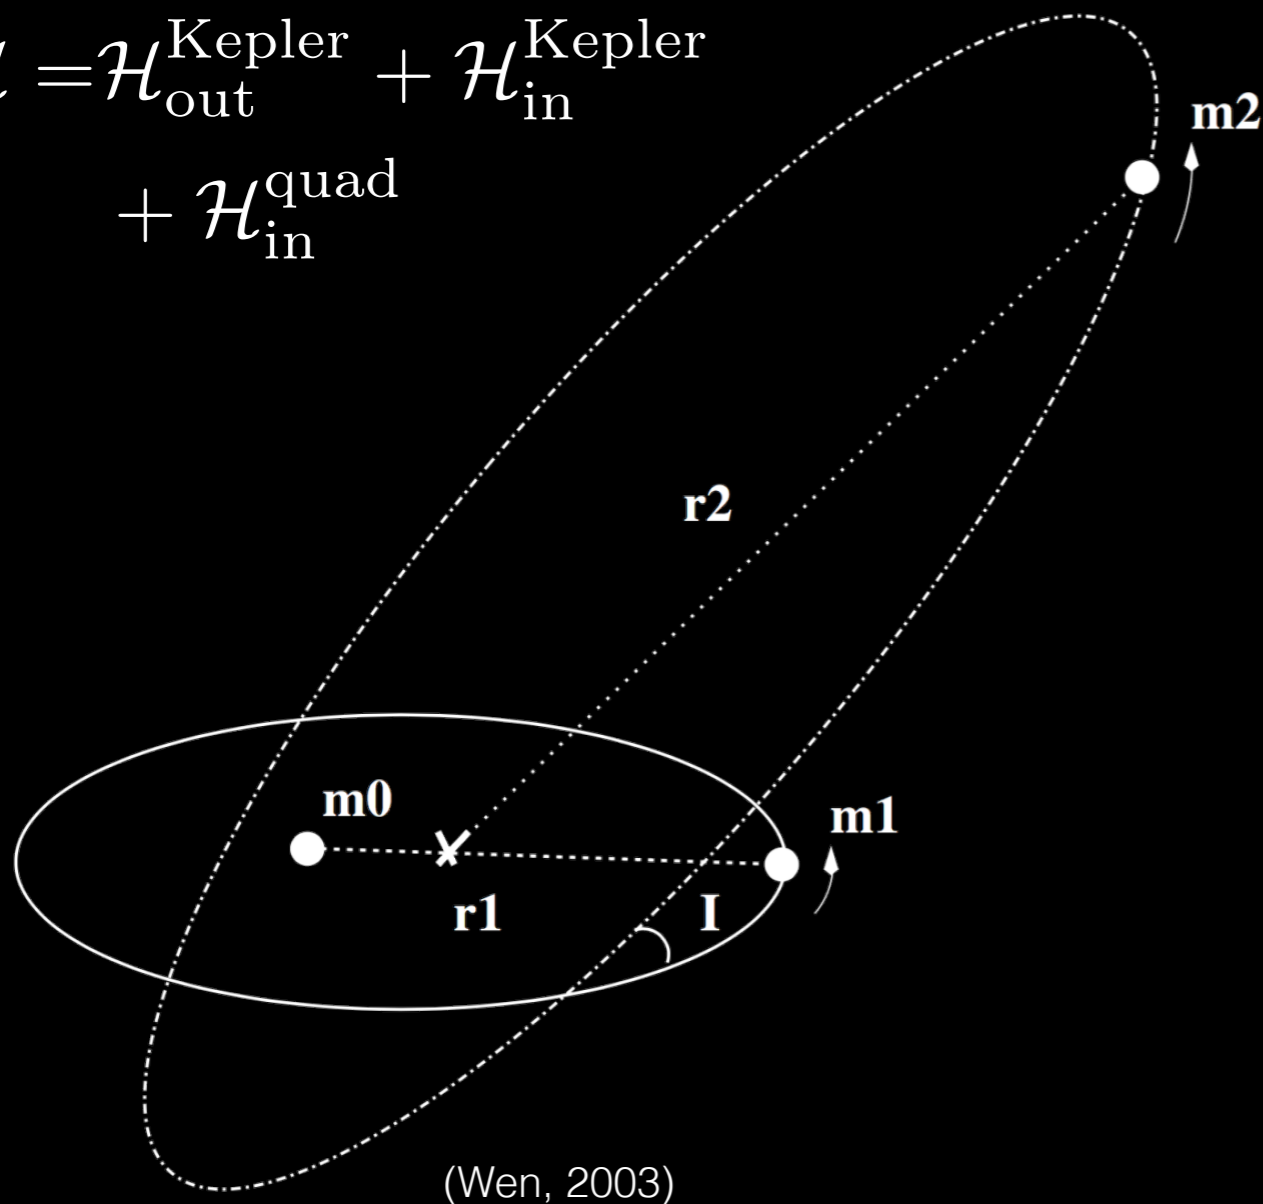

For $t_{\text{merge}} < t_{\text{H}}$, require $P < 0.3$ day for $0.7+0.7 M_{\odot}$

Question: How to produce compact WD binaries?

Proposal: Triple System

Quadrupole order, Secular

$$\mathcal{H} = \mathcal{H}_{\text{out}}^{\text{Kepler}} + \mathcal{H}_{\text{in}}^{\text{Kepler}} + \mathcal{H}_{\text{in}}^{\text{quad}}$$

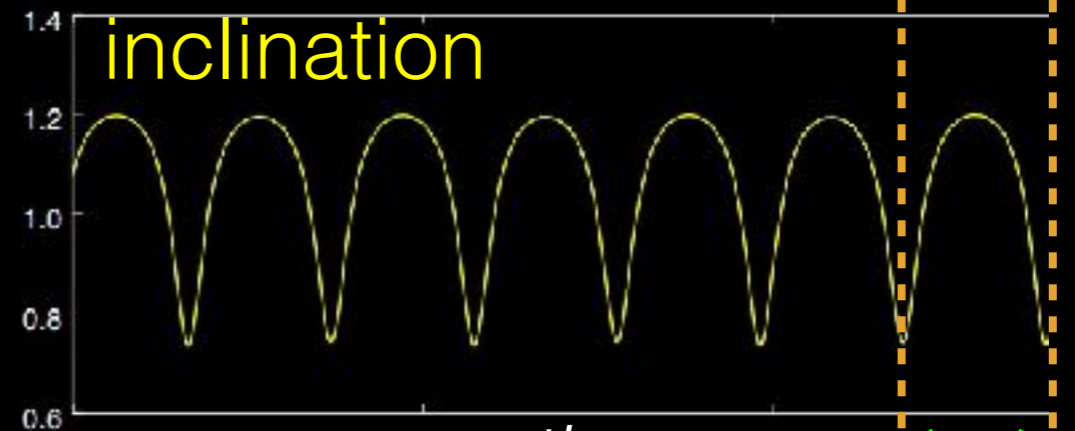

Kozai-Lidov Mechanism

eccentricity

inclination

time

$$t_{\text{KL}} \sim \frac{P_{\text{out}}^2}{P_{\text{in}}}$$

High eccentricity is possibly driven by a distant companion star!

Variants in Triples

- Higher Order Secular Effects

(Katz&Dong, 2011)

- Non-Secular Effects (e.g. Katz&Dong, 2012; Antognini *et al.* 2014)
- Mass Loss (e.g. Shappee&Thompson, 2012)
- ...

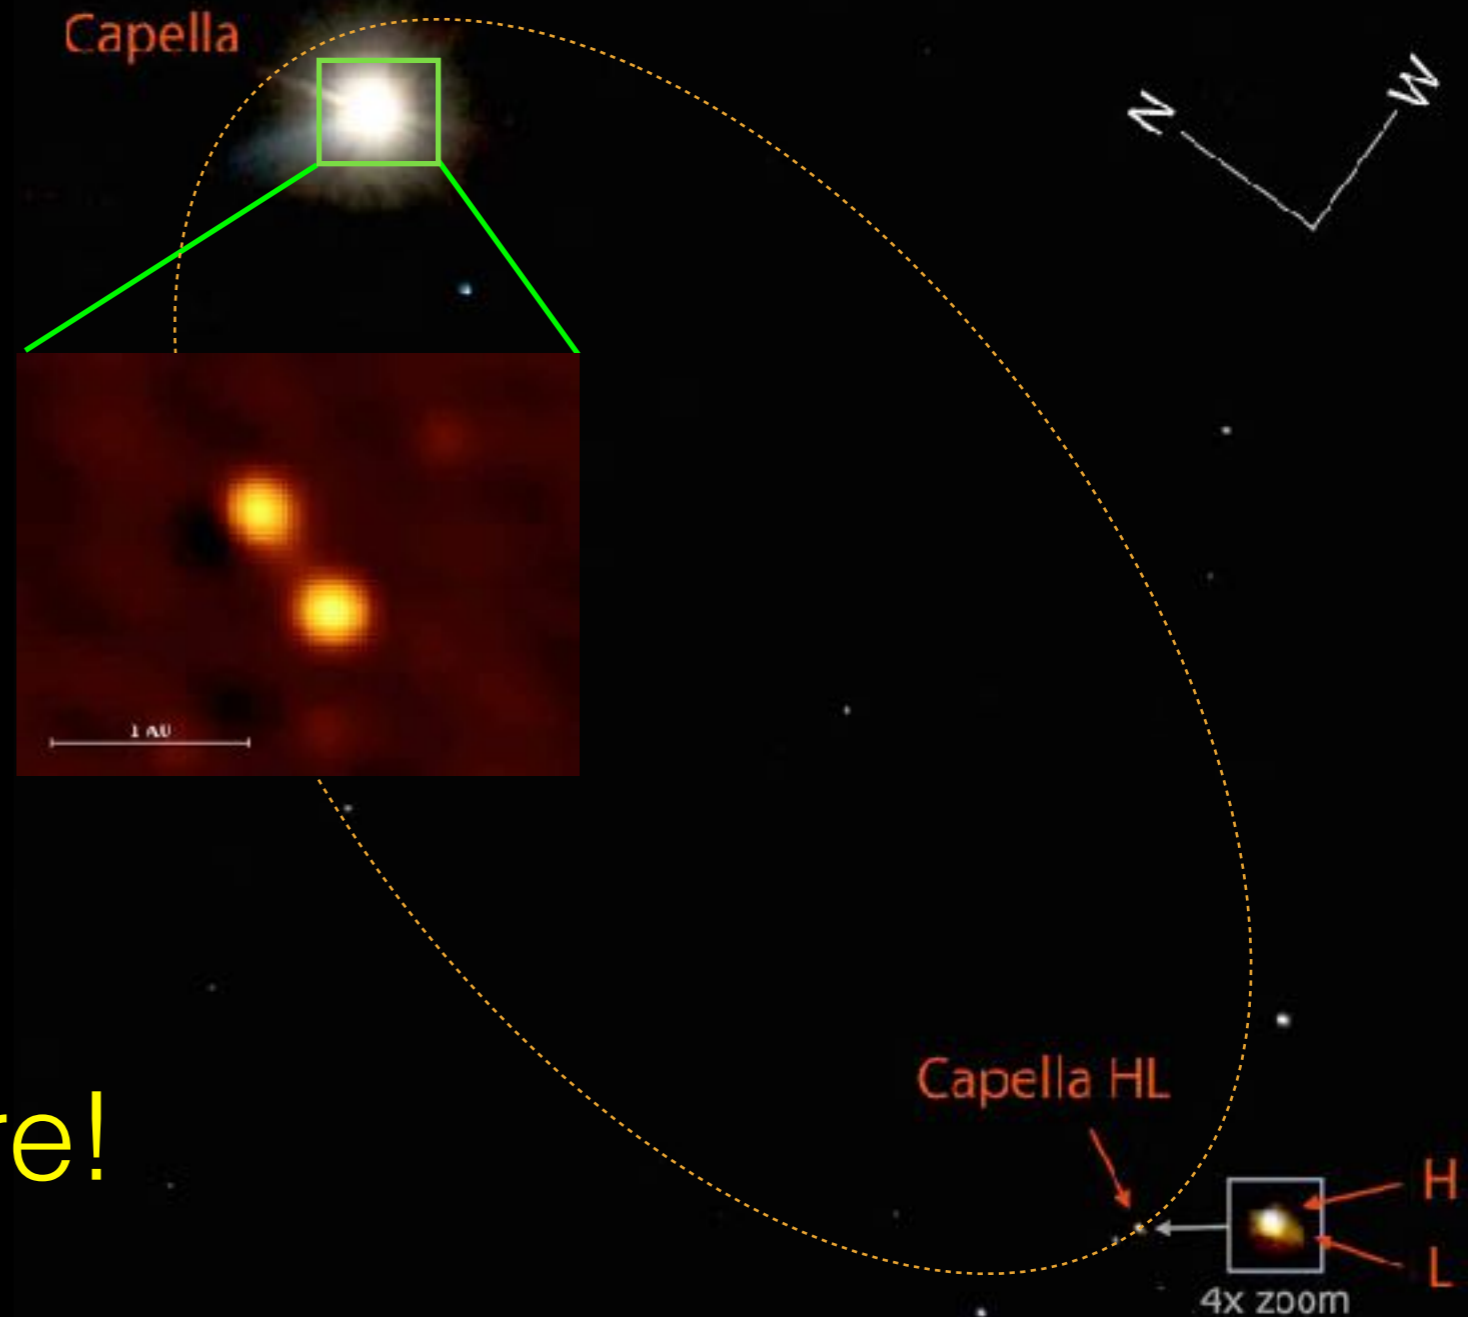

Question Still Open

We Propose: Hierarchical Quadruple

~33%: Binaries
~8%: Triples
~3%: Quadruples
(Raghavan *et al.* 2010)

They are NOT rare!

Why Quadruples?

N-body Simulations (Pejcha *et al*, 2013):

More DOF; can be irregular \longrightarrow More Mergers?

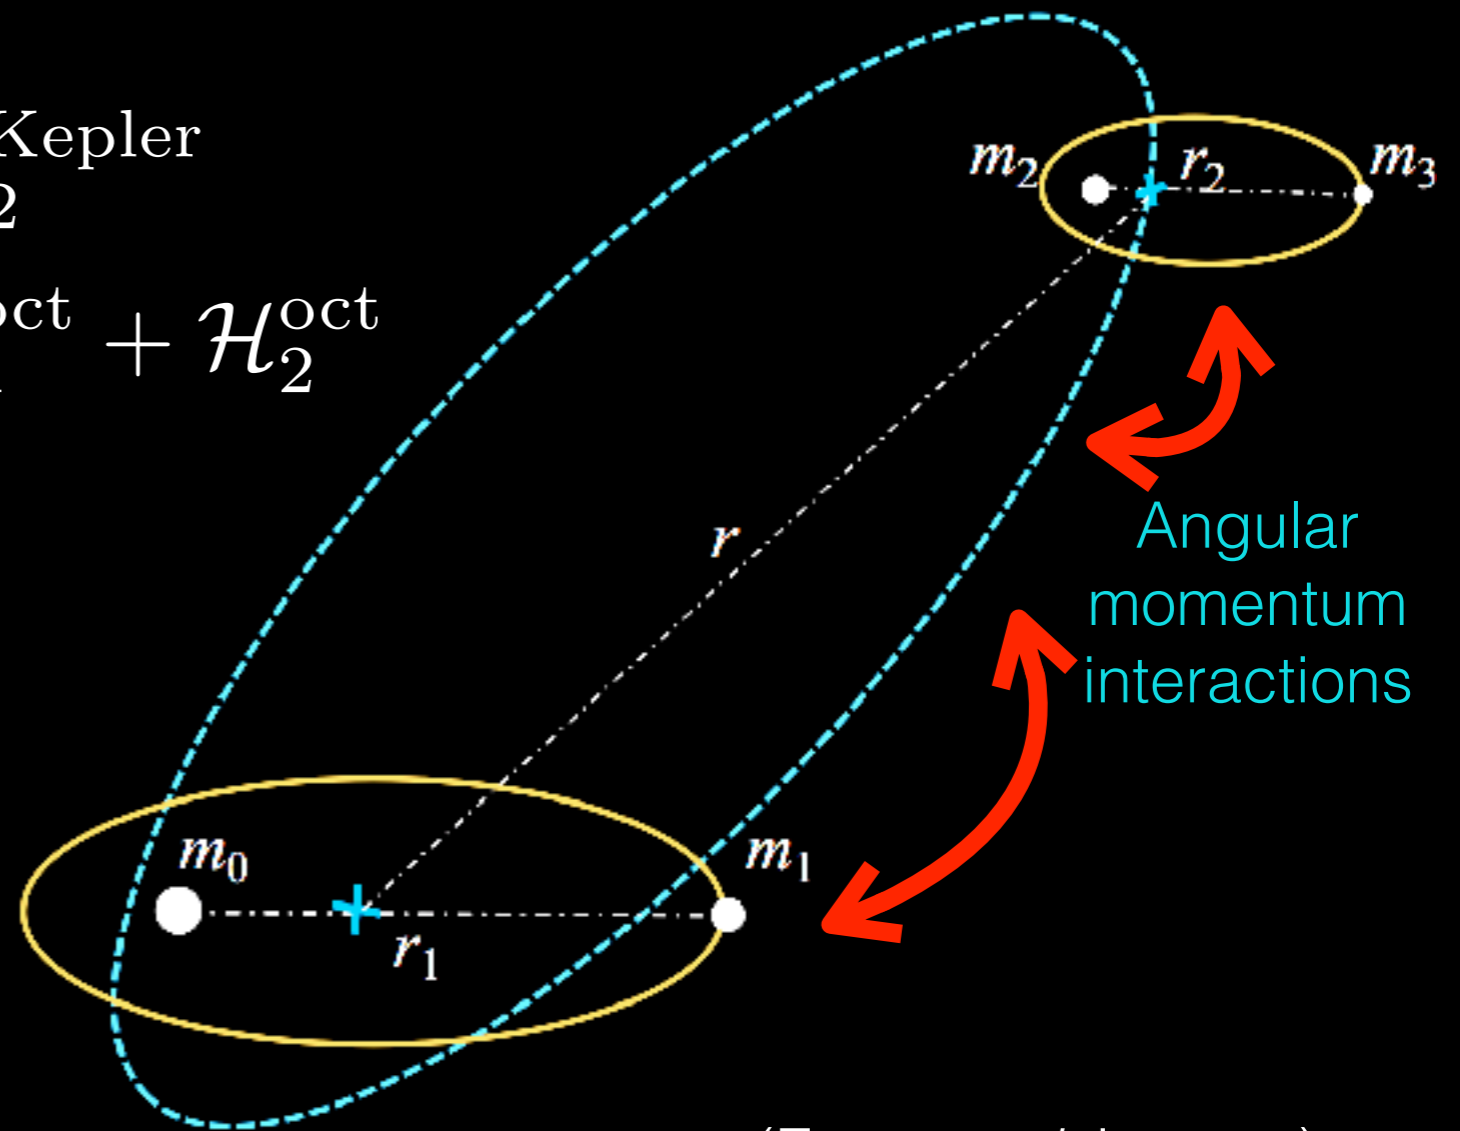

Secular Dynamics of Quads in a Nutshell

$$\mathcal{H} = \mathcal{H}_{\text{mutual}}^{\text{Kepler}} + \mathcal{H}_1^{\text{Kepler}} + \mathcal{H}_2^{\text{Kepler}} \\ + \mathcal{H}_1^{\text{quad}} + \mathcal{H}_2^{\text{quad}} + \mathcal{H}_1^{\text{oct}} + \mathcal{H}_2^{\text{oct}} \\ + \dots$$

Orbital Averaging

Canonical Variables:
6 for each orbit

12 coupled secular EoMs in total!

(Fang *et al*, in prep)

[(Star+Star) + (Star+Star)]: Both irregular behavior

(Fang *et al*, in prep)

WD-WD in Quads

Effects Included:

Secular: Quadrupole + Octupole

GR: 1PN precession + GW

Tide: precession + dissipation

Example of
Orbital Decay

(Fang *et al*, in prep)

WD-WD in Quads

Circularization

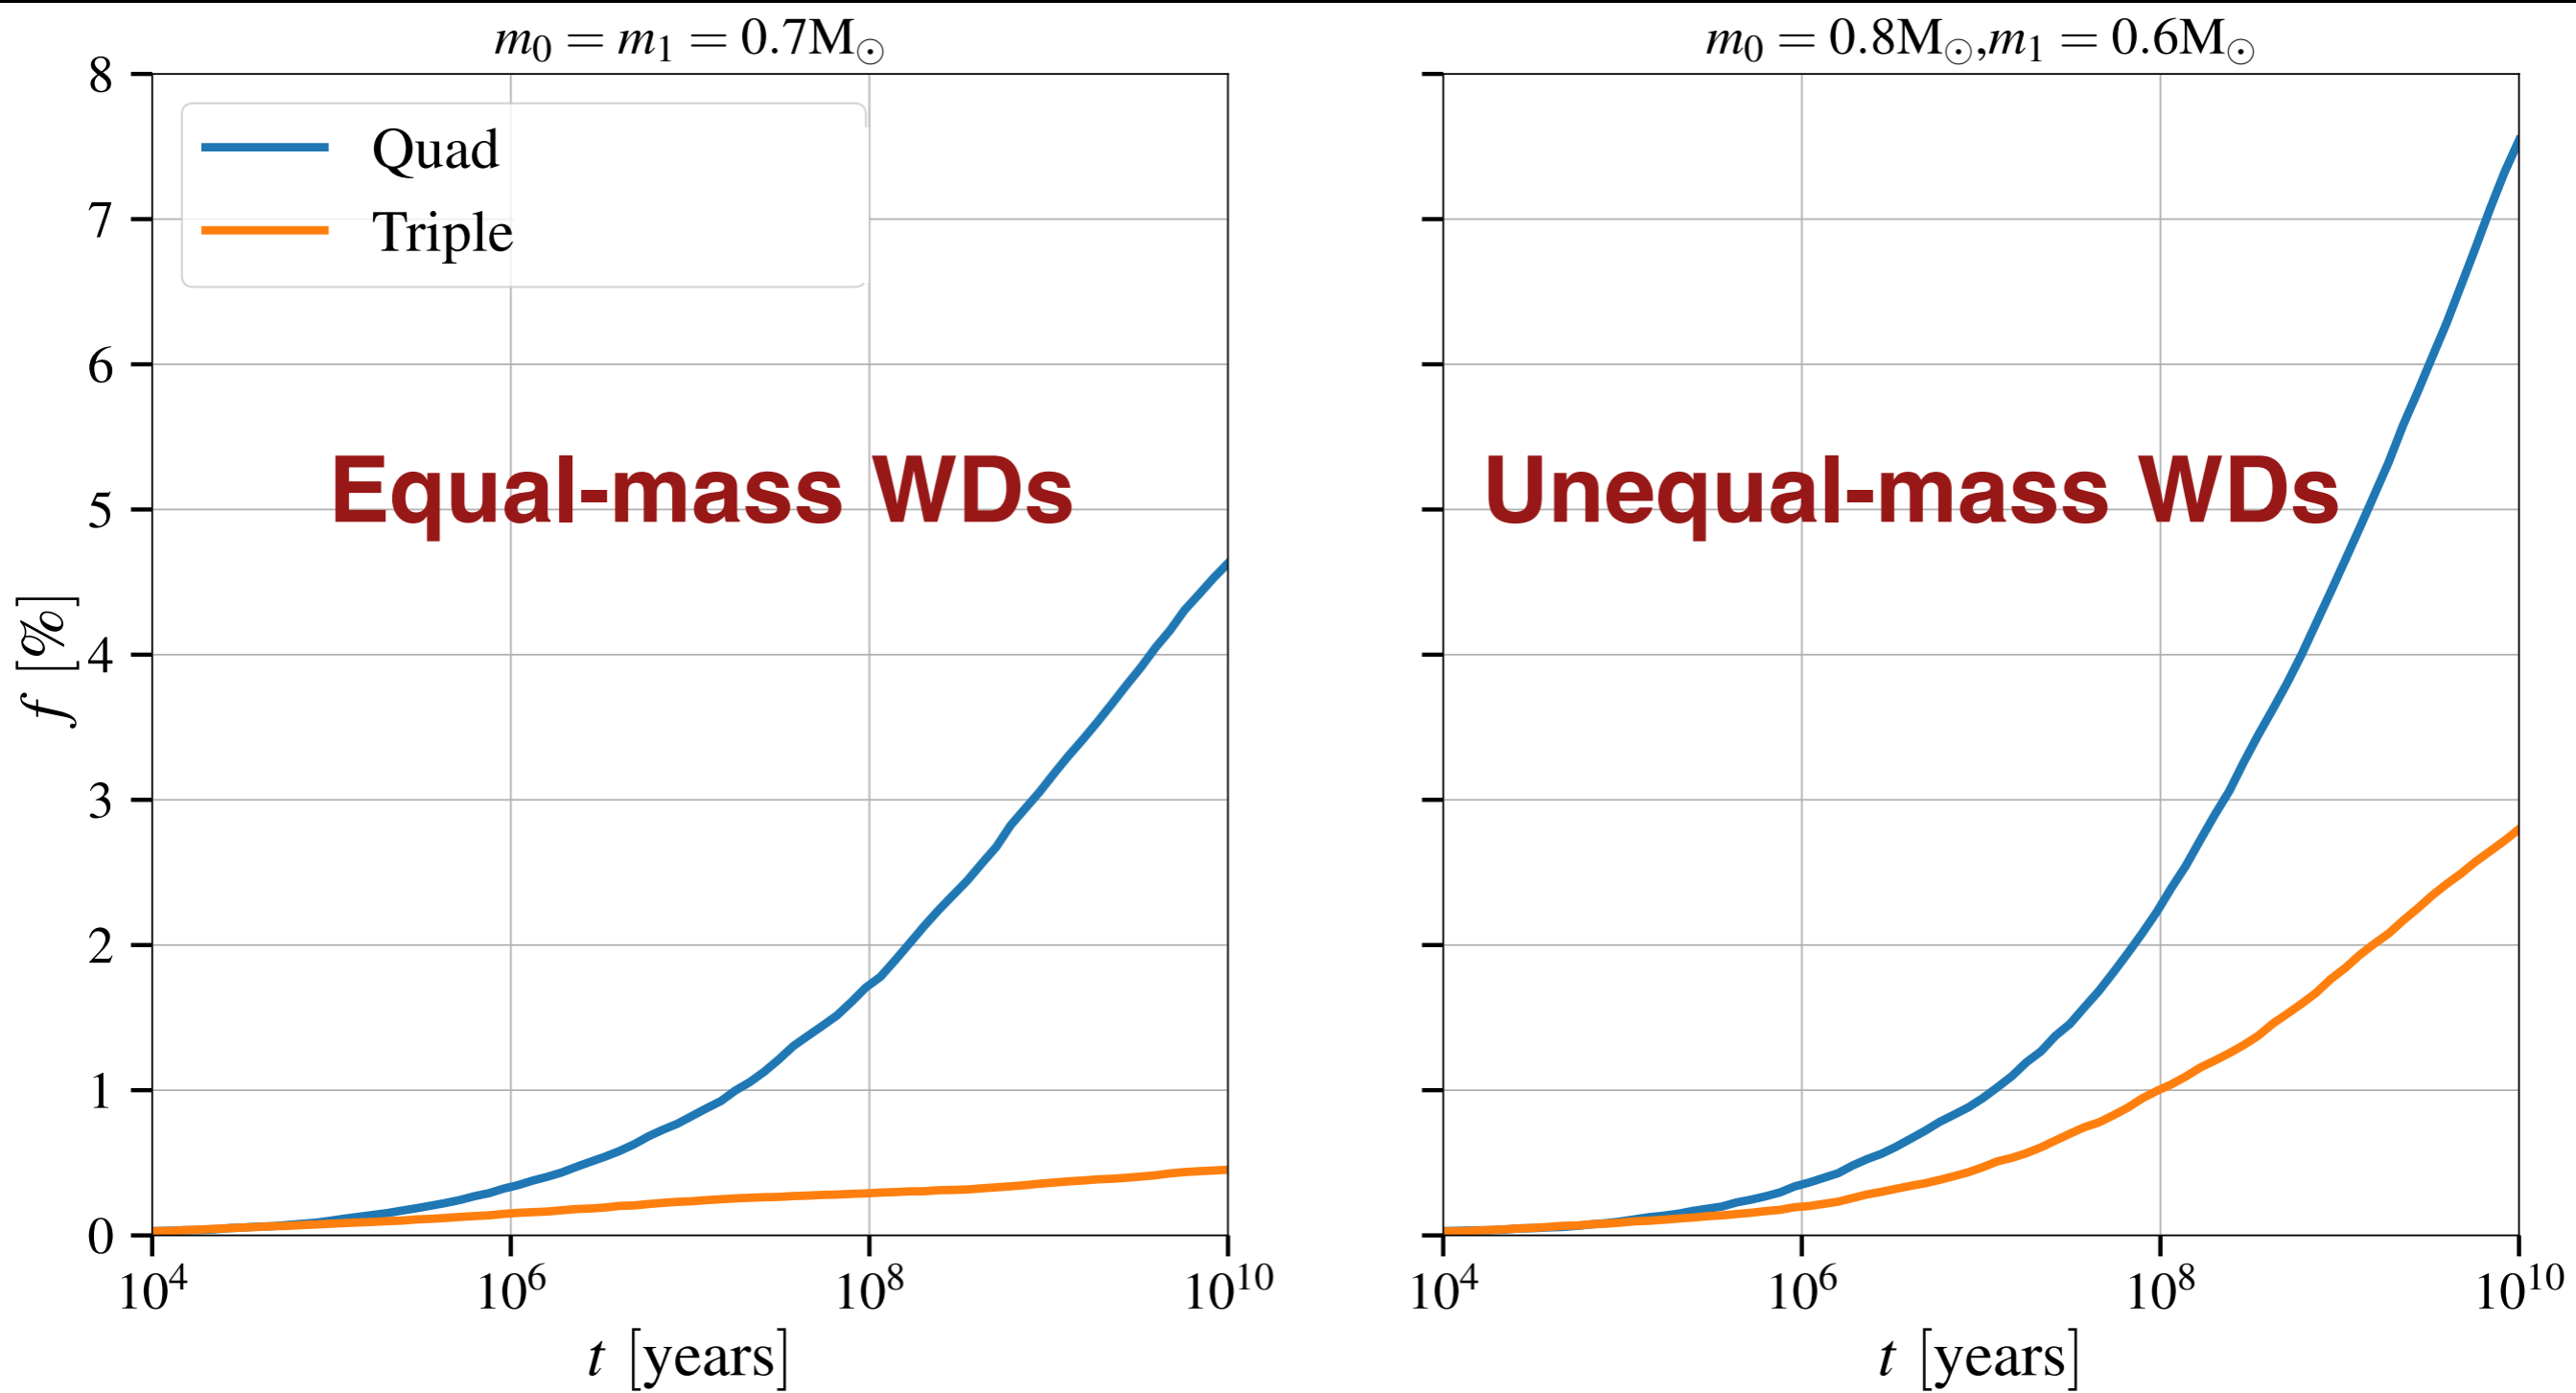

Orbit shrinks

Inclination Freezes

WD-WD in Quads

Full Run: 10^5 sys, orbital sizes/shapes sampled

Quadruples provide much more mergers than triples in secular calculations!

(Fang *et al*, in prep)

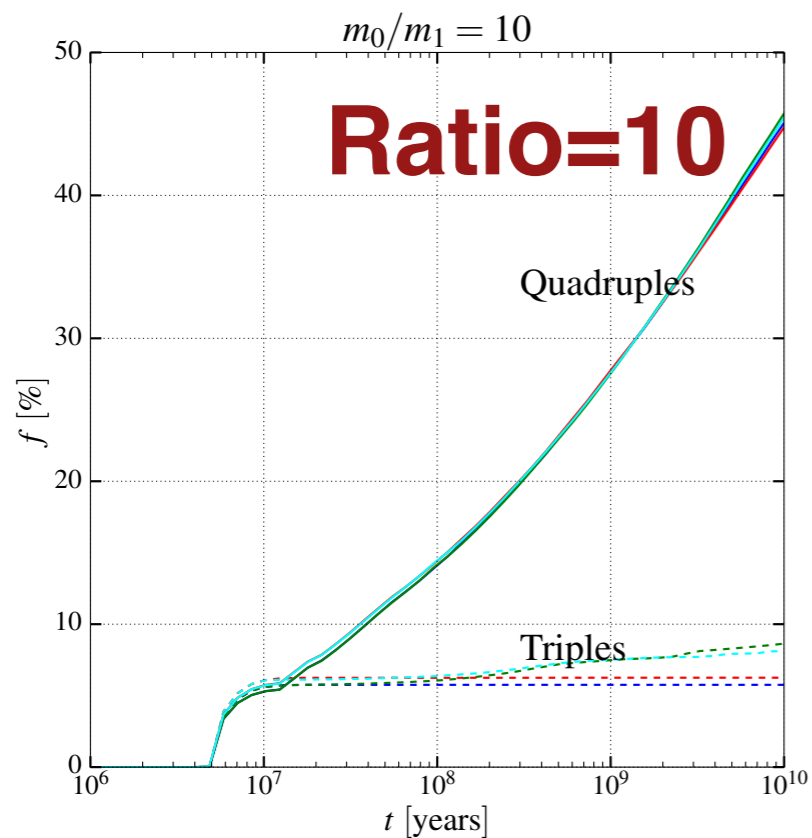

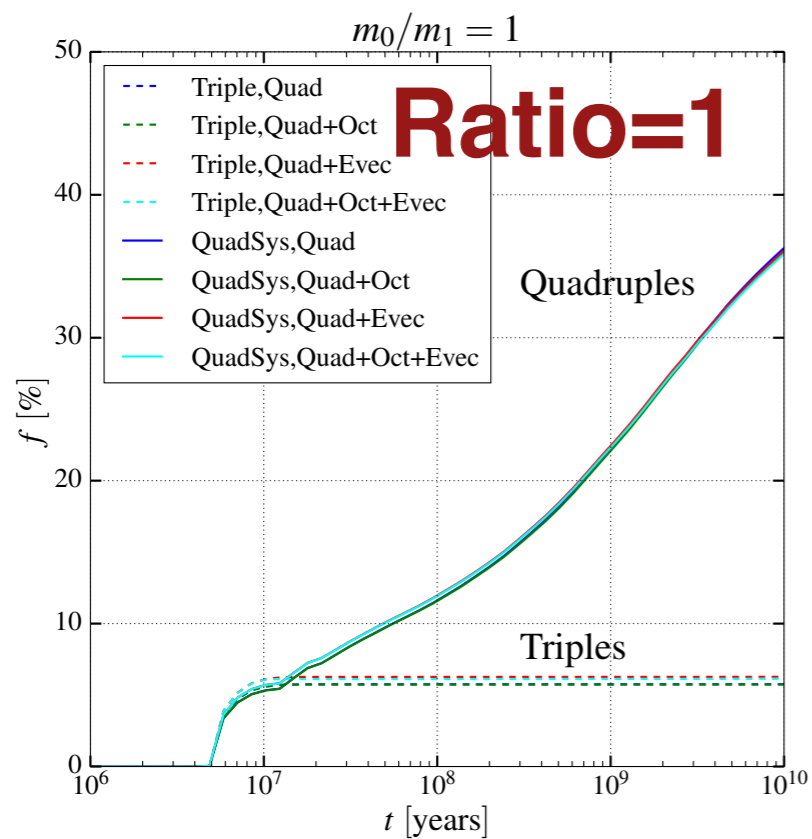

Summary

Hierarchical Quadruple Systems:

- Much richer secular dynamics than triples
- Higher high- e fraction, hence more compact objects or mergers
- Might contribute significantly to WD-WD mergers, hence (possibly) SN Ia rate

BACKUP SLIDES

Quadruples vs. Triples

True for different mass ratios!

Quadruples vs. Triples

High-e Fraction at t=5Gyr

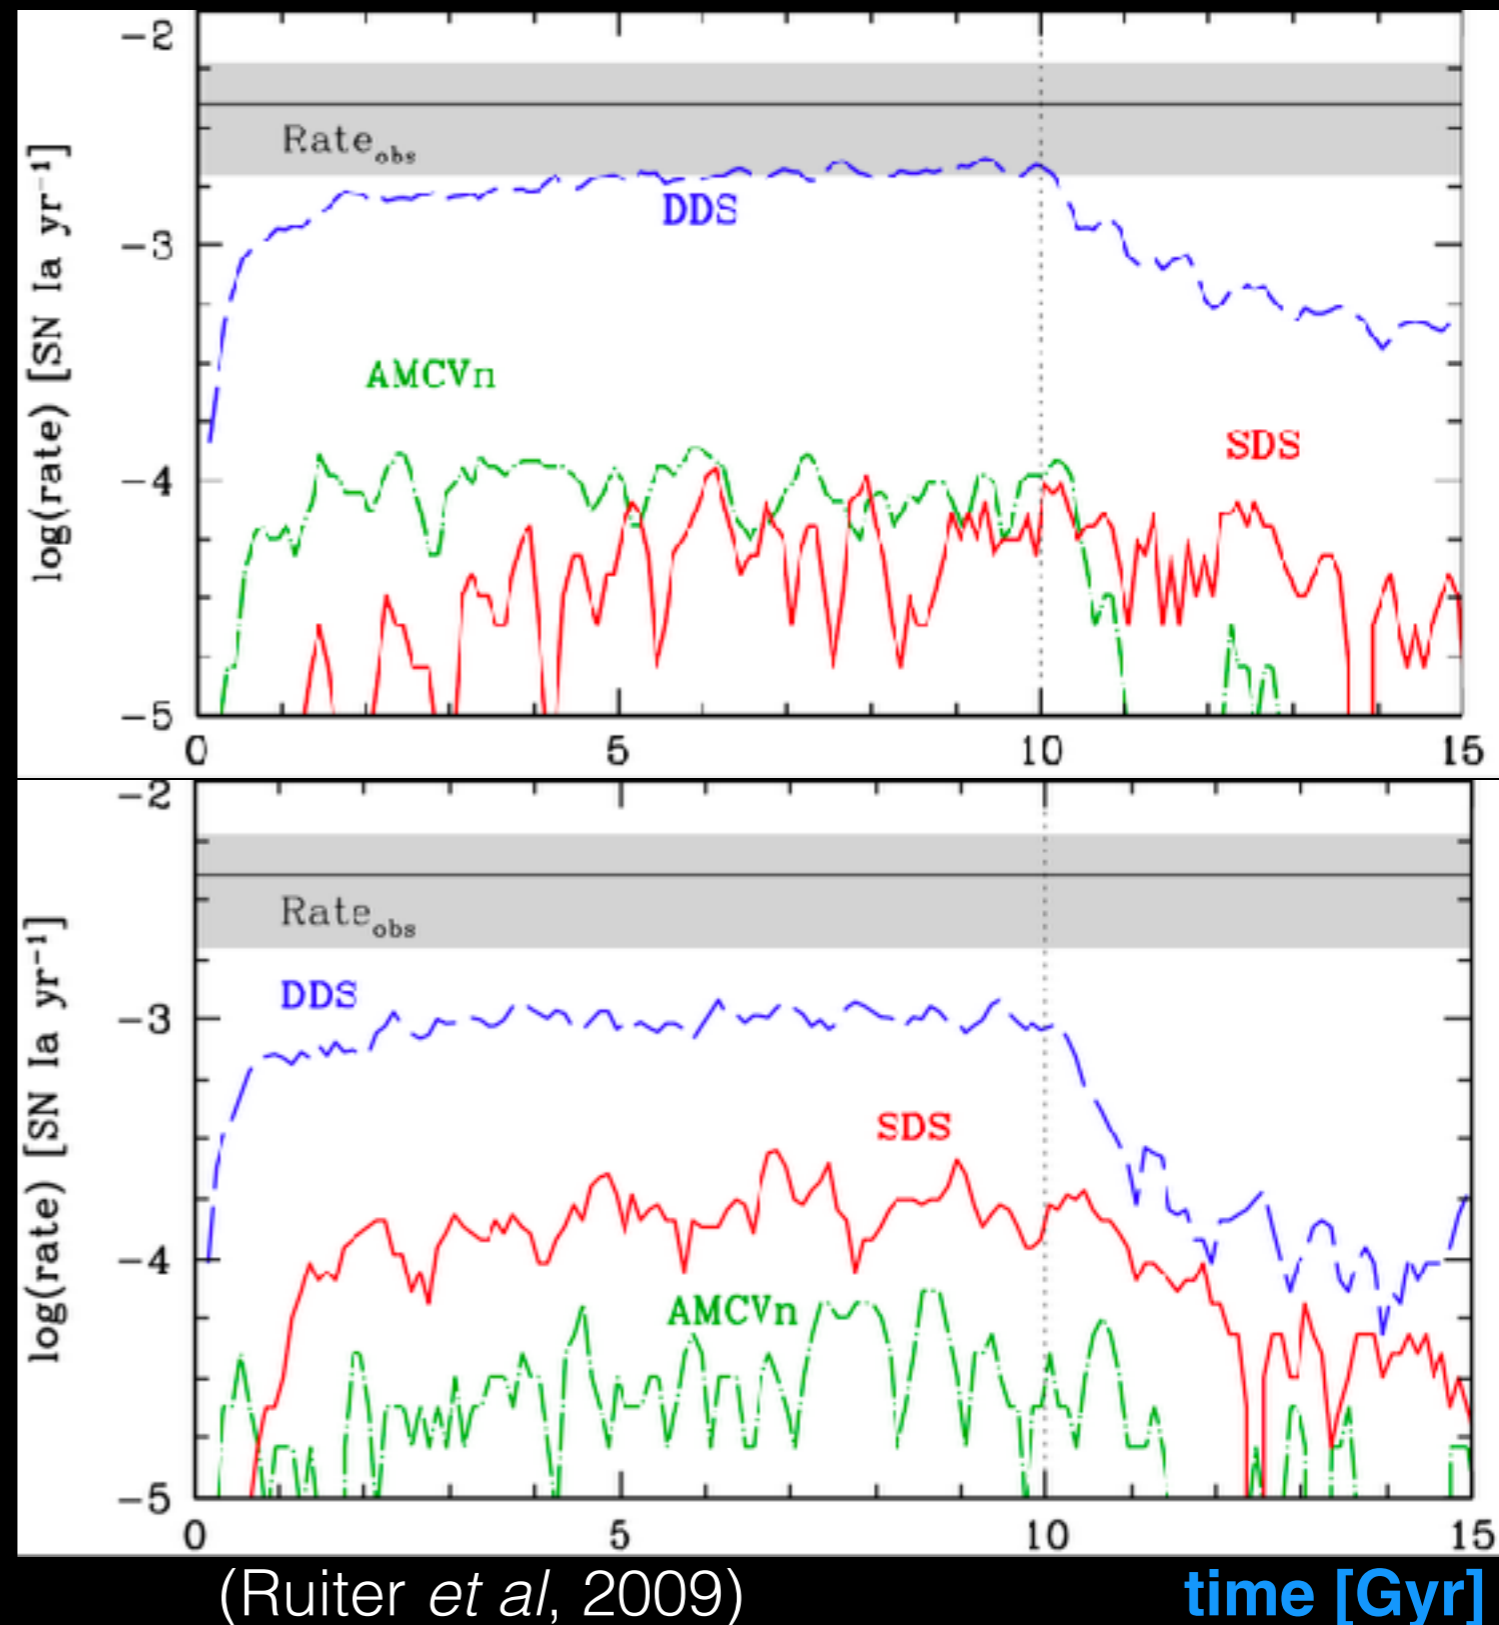

True for different orbital sizes!

Proposal: Common Envelope Evolution

- Orbit rapidly shrinks in CE phase
- Underpredict short time-delay SN rate
- Depend on CE evolution physics, ...

Unclear

(Ruiter *et al*, 2009)

time [Gyr]

Proposal: Triple System

$$e_{\max} = \sqrt{1 - \frac{5}{3} \cos^2 i}$$
$$t_{\text{GW}} \sim a_1^4 (1 - e_1^2)^{7/2}$$

} **Largely shorten merger time**

(e.g. Peter, 1964; Blaes *et al*, 2002)

Thompson (2011): $t_{\text{merge}} \sim \cos^6 i$

Concerns:

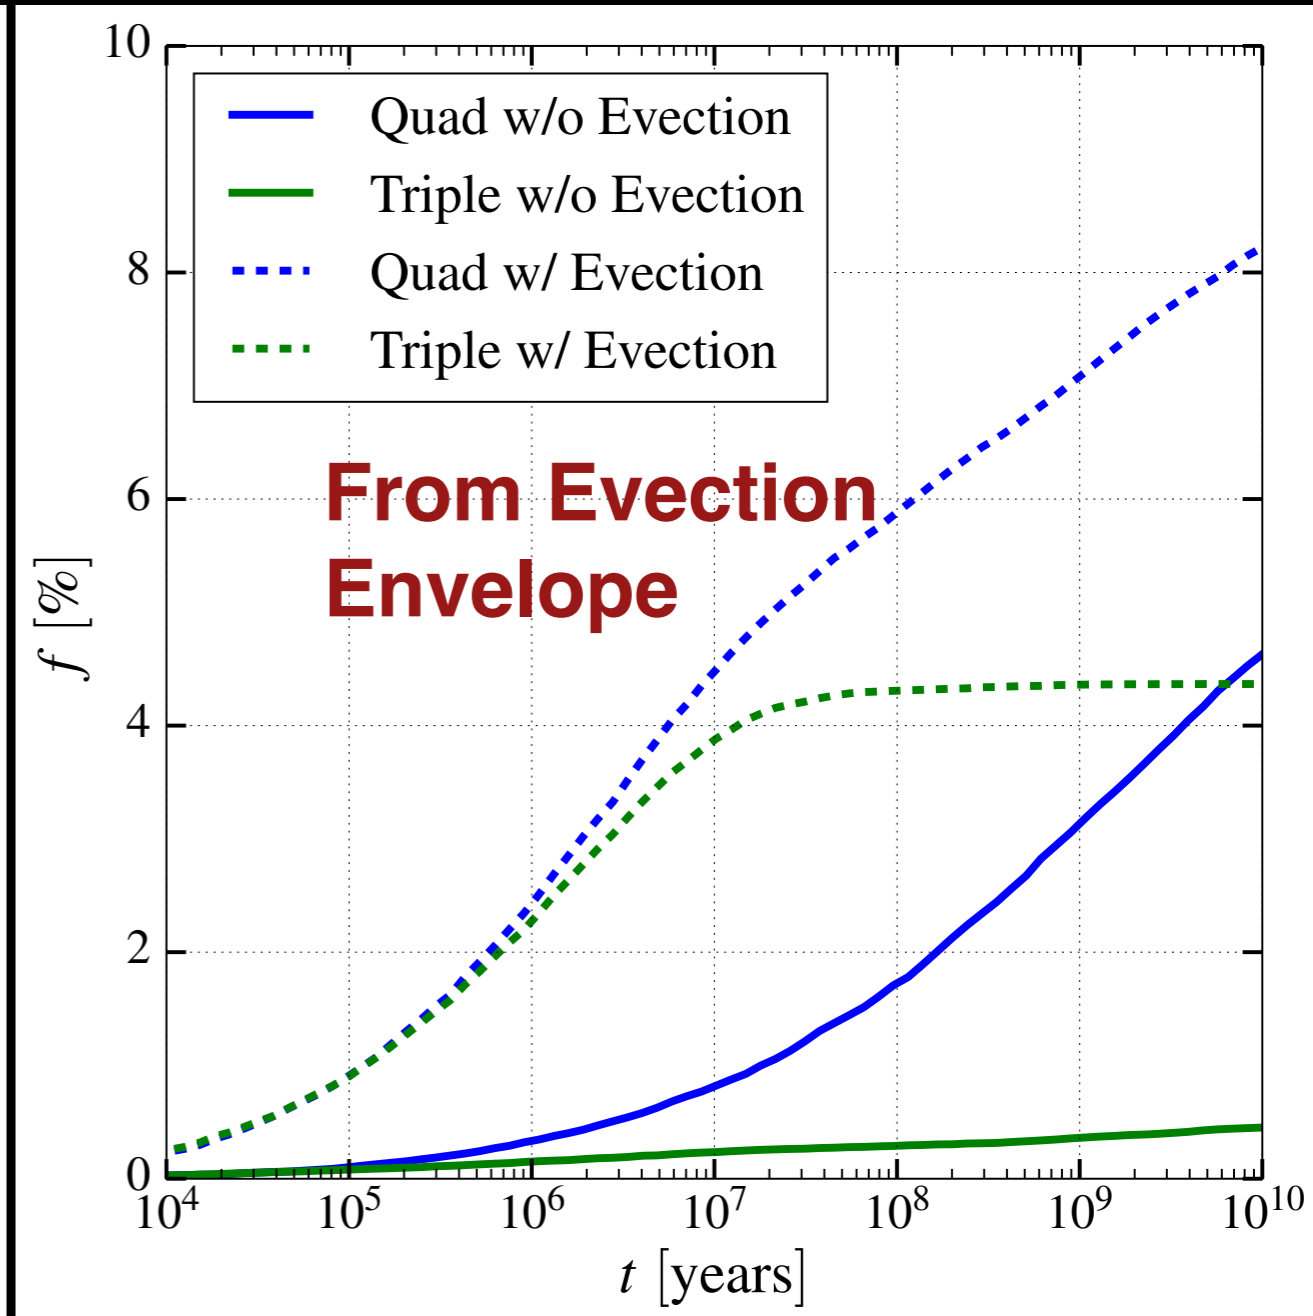

- Require high initial inclination
- Mergers in main sequence: not helpful to SN *Ia*

Issue

Non-secular: Evection \rightarrow Direct Collisions

(Antognini et al. 2014)

(Fang et al, in prep)

More careful evection treatment needed!

[(Star+Planet) + (Star+Star)]: Regular vs irregular behavior

(Fang *et al*, in prep)

Quadruples vs. Triples

100,000 Systems with Random Orientations

Stop at 10Gyr or when $r_{\text{peri}} < 6R$

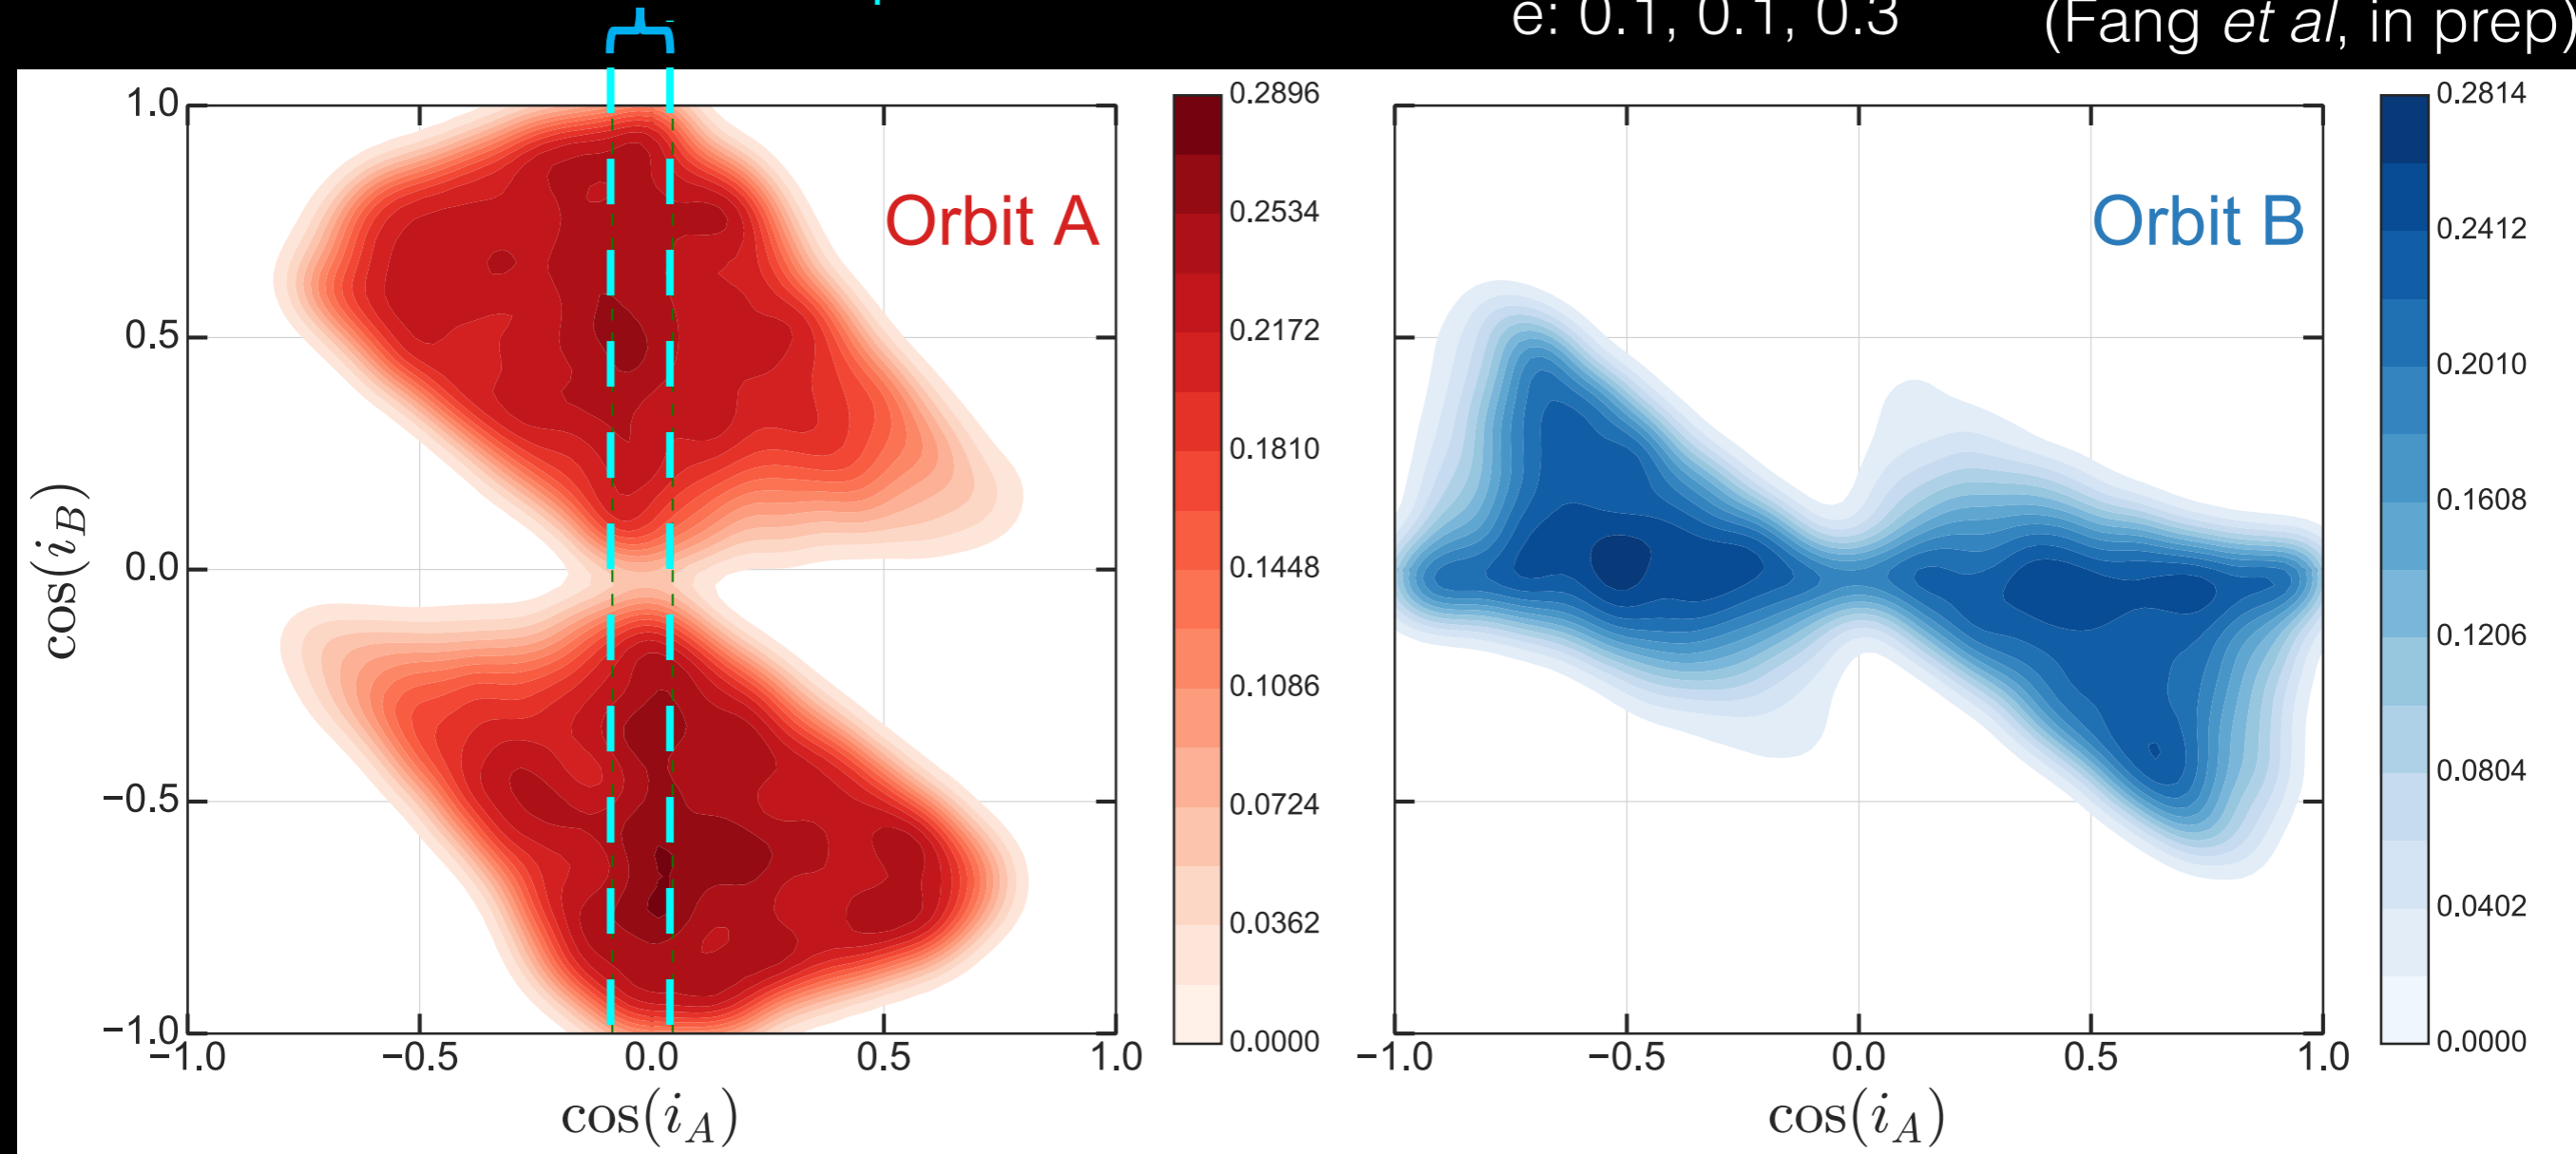

Constraint for triple limit

$m: (1+1)+(1+1)M_{\odot}$

$a: 10, 15, 1000\text{AU}$

$e: 0.1, 0.1, 0.3$

(Fang *et al*, in prep)

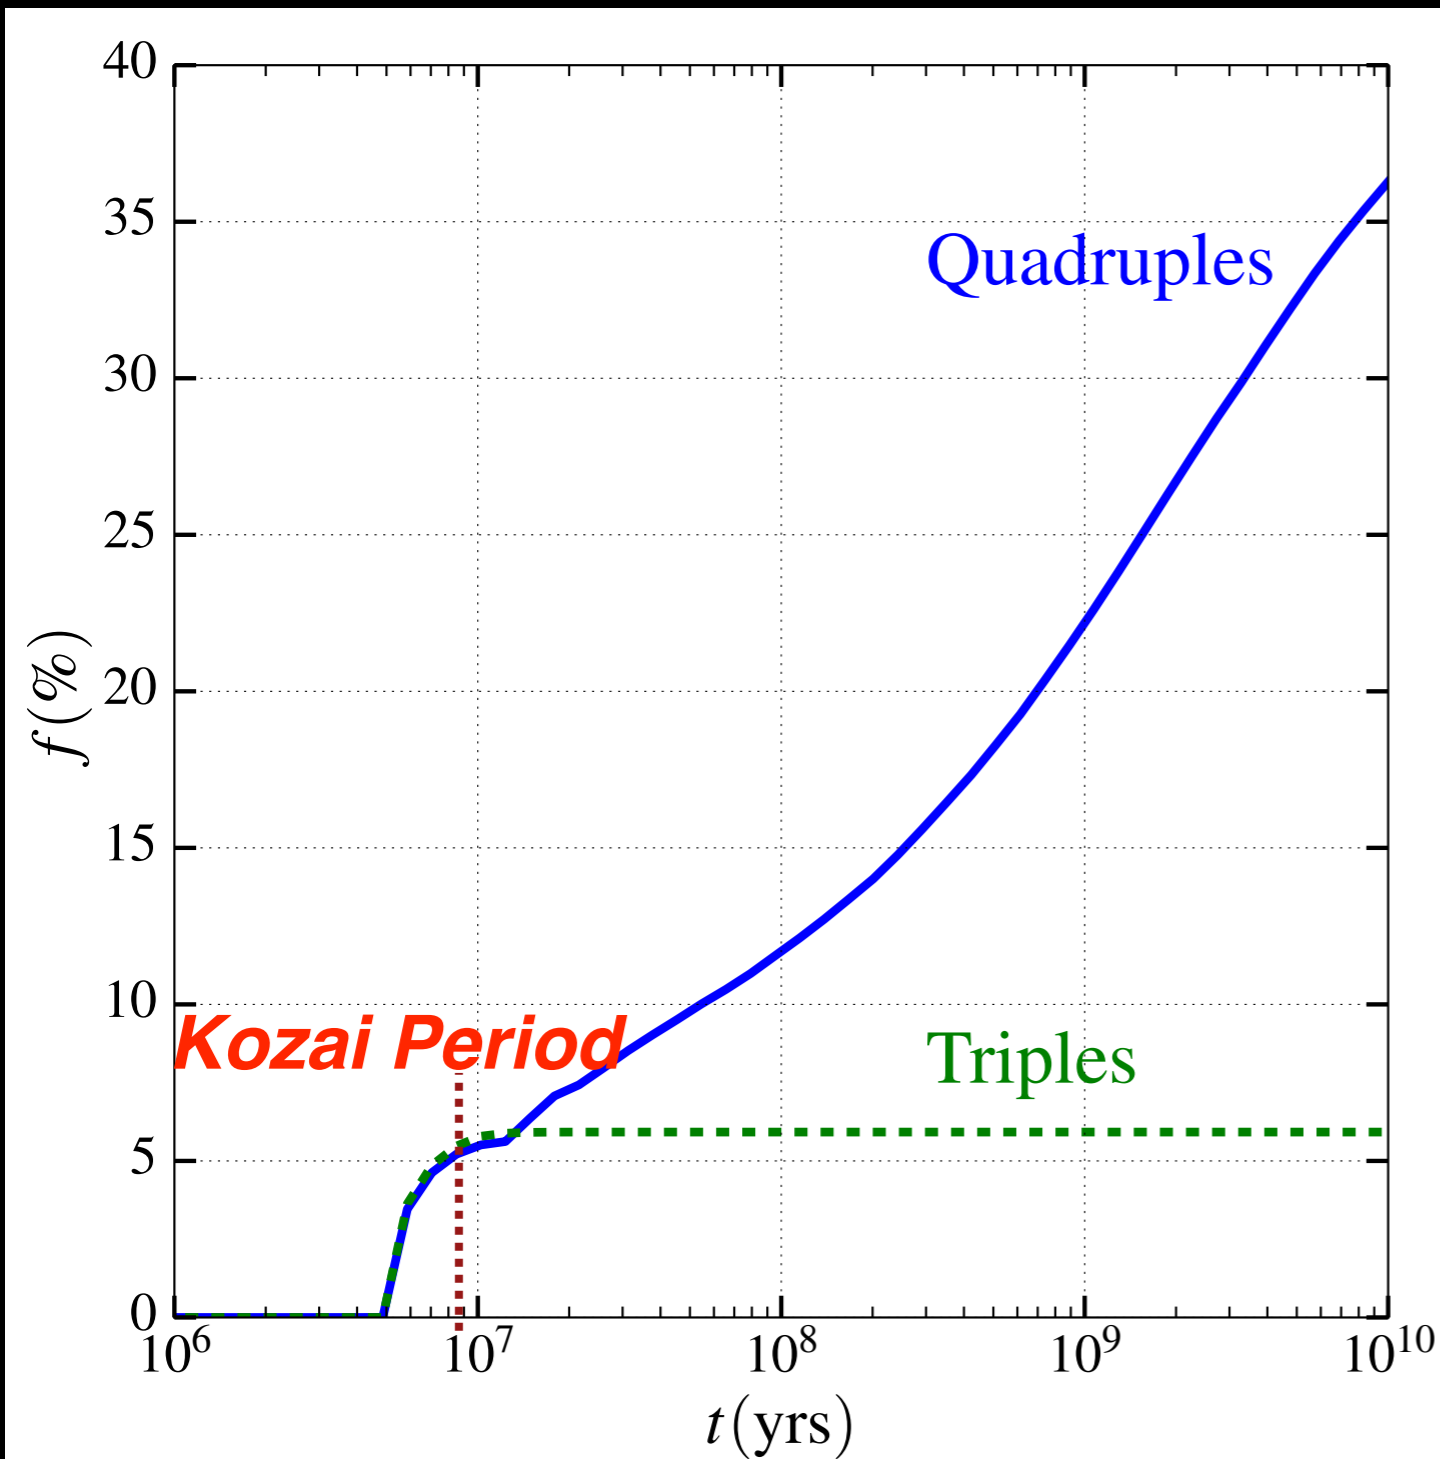

Quadruples: Much weaker requirement for inclination

Quadruples vs. Triples

100,000 Systems with Random Orientations

High- e fraction vs. time

Quads At Quad Order:

- Much higher fraction
- Near linear growth in $\log(t)$

Are they true for other orbital configurations?

Yes!

- mass ratios
- orbital sizes

(Fang *et al*, in prep)
