ABRACADABRA: A novel approach to detecting axion dark matter

Thursday 10 August 2017 16:00 (15 minutes)

ABRACADABRA is a proposed experiment to search for ultralight (10^{-14} - 10^{-6} eV) axion dark matter. When ultralight axion dark matter encounters a static magnetic field, it sources an effective electric current that follows the magnetic field lines and oscillates at the axion Compton frequency. In the presence of axion dark matter, a large toroidal magnet will act like an oscillating current ring, whose induced magnetic flux can be measured by an external pickup loop inductively coupled to a SQUID magnetometer. The readout circuit can be broadband or resonant and both are considered. ABRACADABRA is fielding a 10-cm prototype in 2017 with the intention of scaling to a 1m^3 experiment. The long term goal is to probe QCD axions near the GUT-scale. In this talk I will review the design, sources of noise, and sensitivity of the experiment.

Author: SAFDI, Benjamin (massachusetts institute of technology)

Presenter: SAFDI, Benjamin (massachusetts institute of technology)

Session Classification: Dark matter

Track Classification: Dark matter (direct detection, indirect detection, theory, etc.)
