N.C.S.R. “Demokritos”

# Why RIB's ?

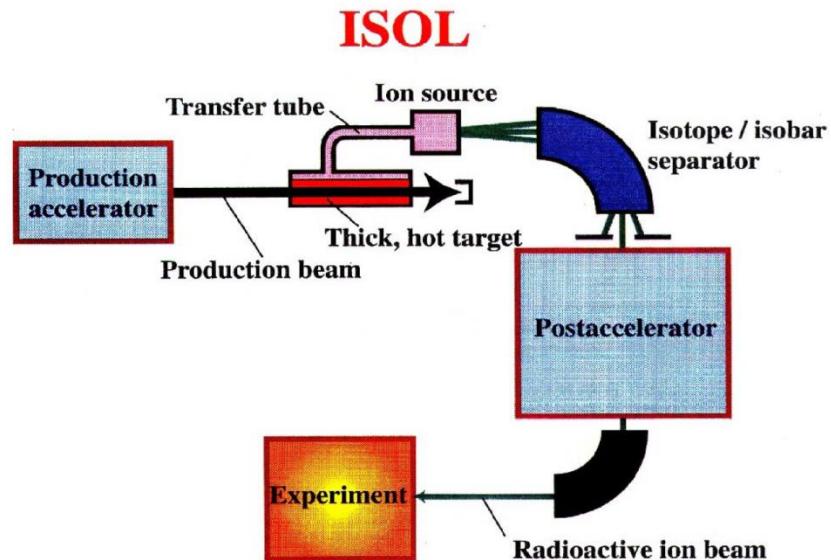

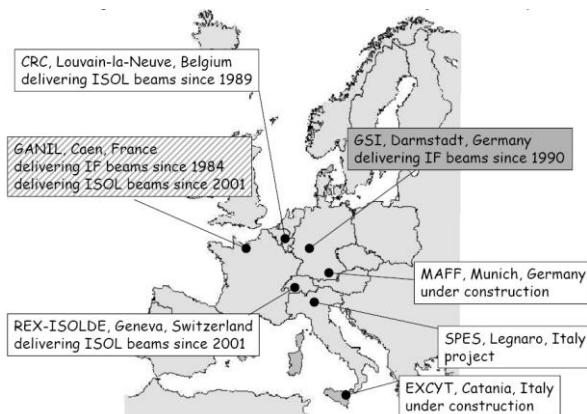

# Production of RIB

## Projectile Fragmentation

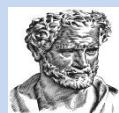

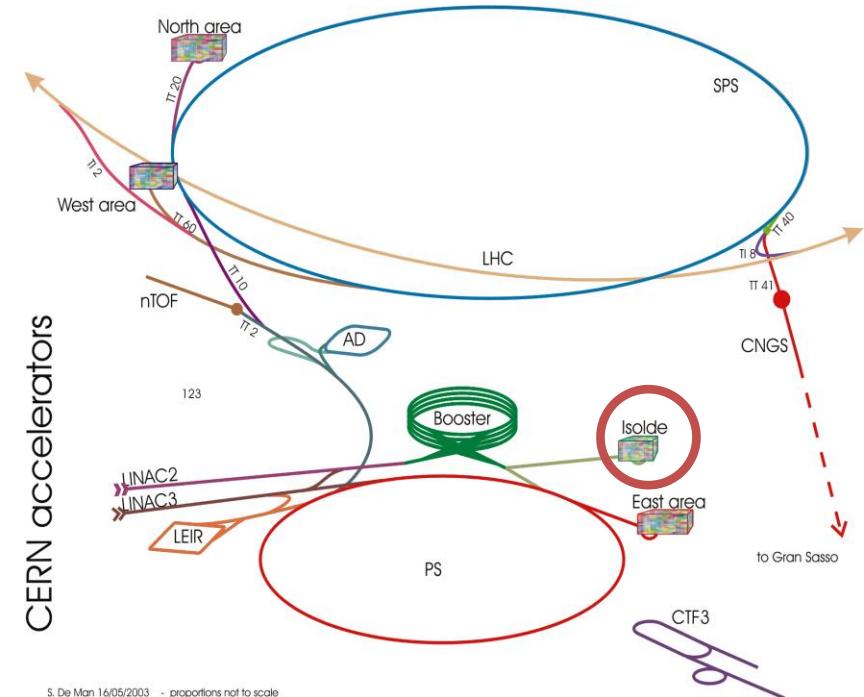

- Time limit  $\sim 1 \mu\text{s}$
- High luminosity
- High energy beam  $>100 \text{ MeV/u}$
- No chemistry

- Time limit  $\sim 10-100 \text{ ms}$
- High beam intensity close to stability
- Better beam quality (purity, optics ...)
- Nuclei produced at rest

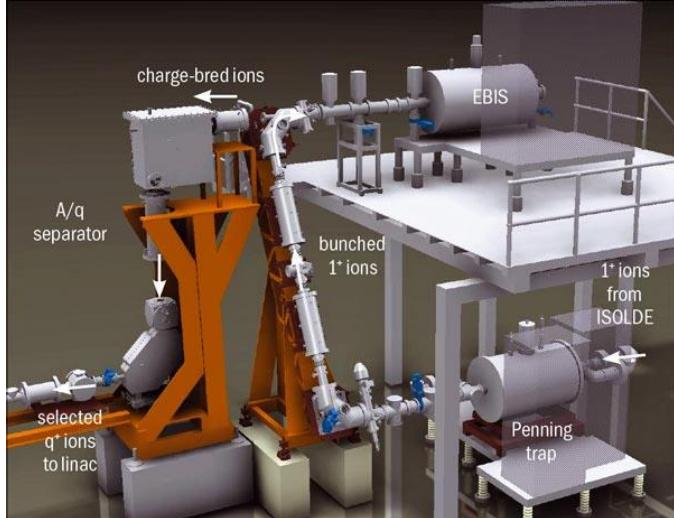

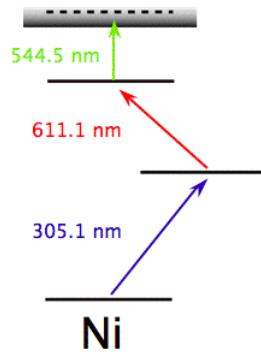

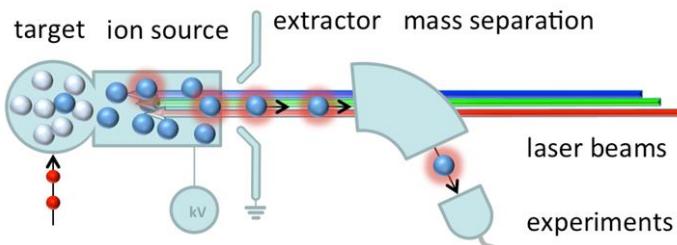

# CERN

# ISOLDE

## Resonance Ionization Laser Ion Source

**REXTRAP**

Penning trap, slowing down ions,  
accumulation and bunching

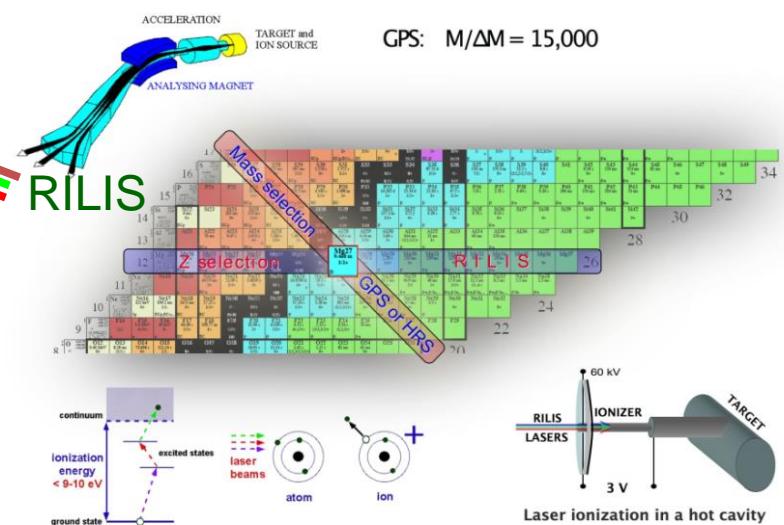

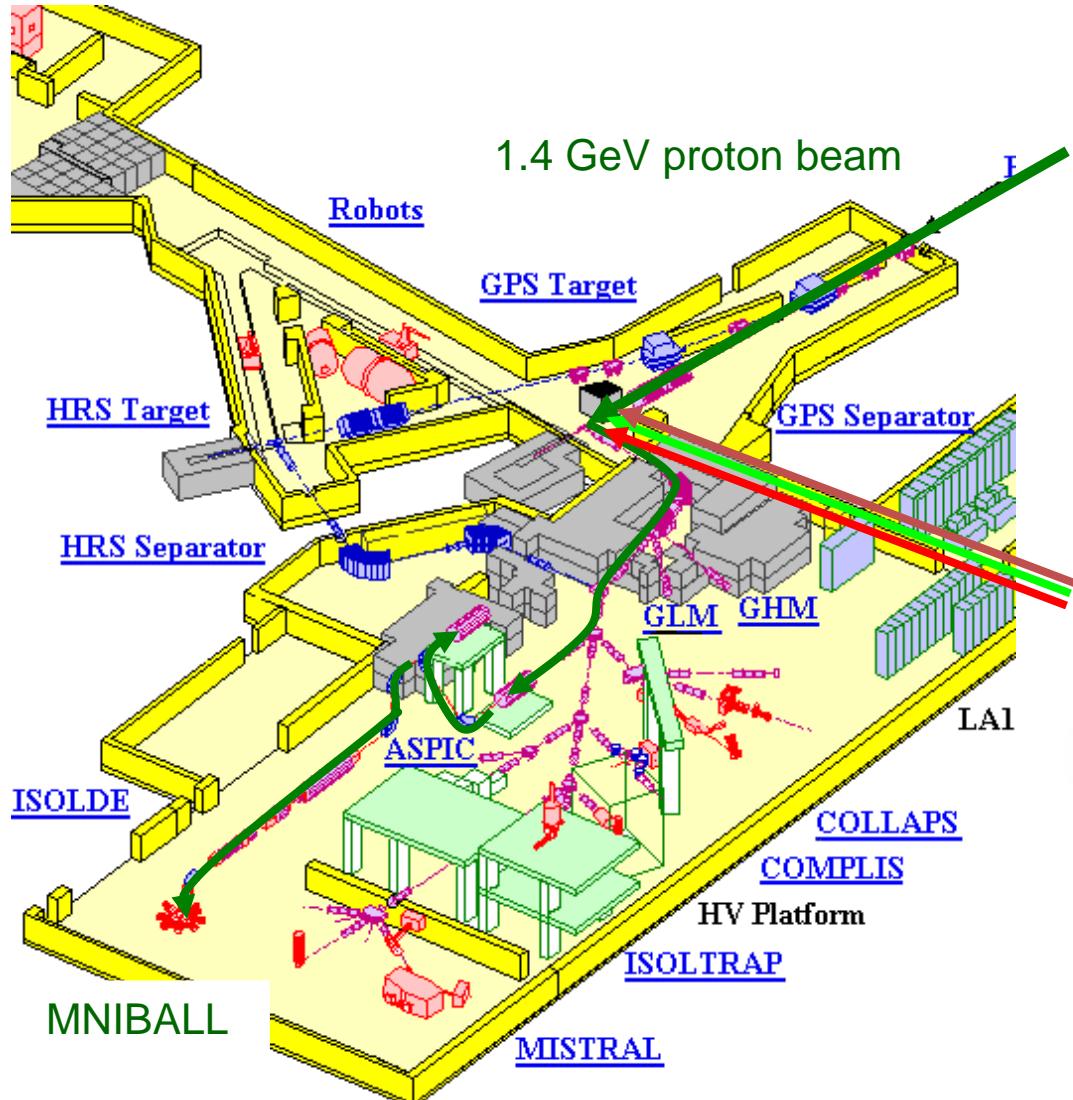

**REXEgis**

Electron Beam Ion Source  
Charge breeding

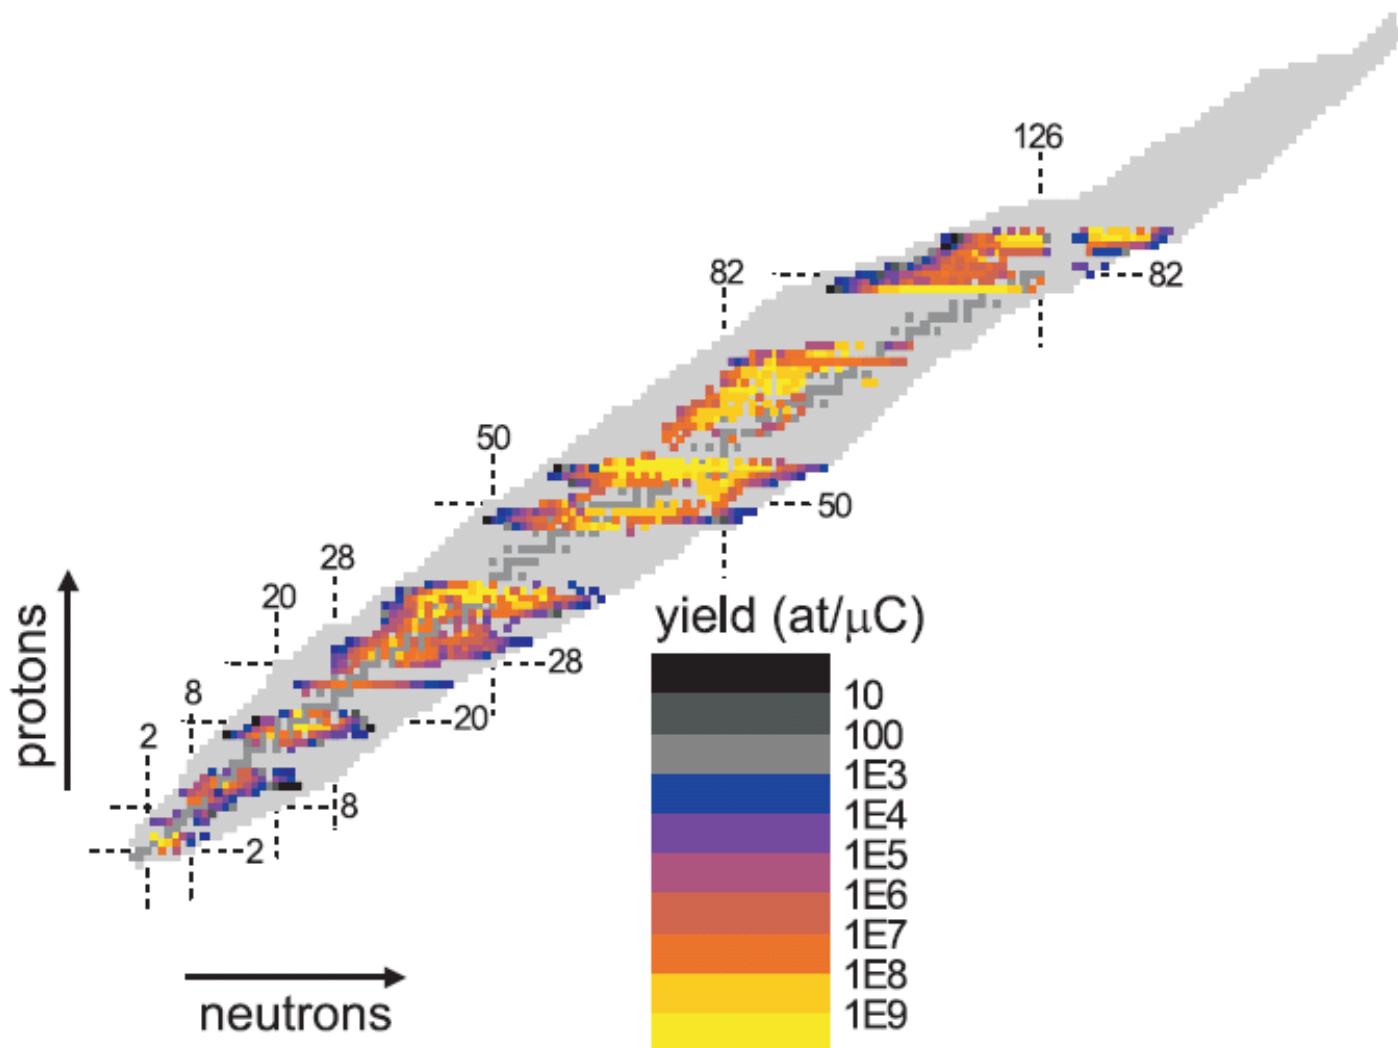

**Mass separator**

$A/q < 4.5$

# ISOLDE

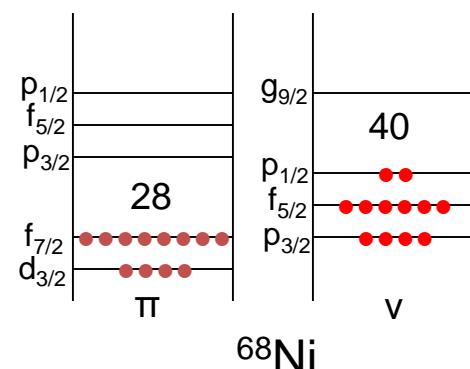

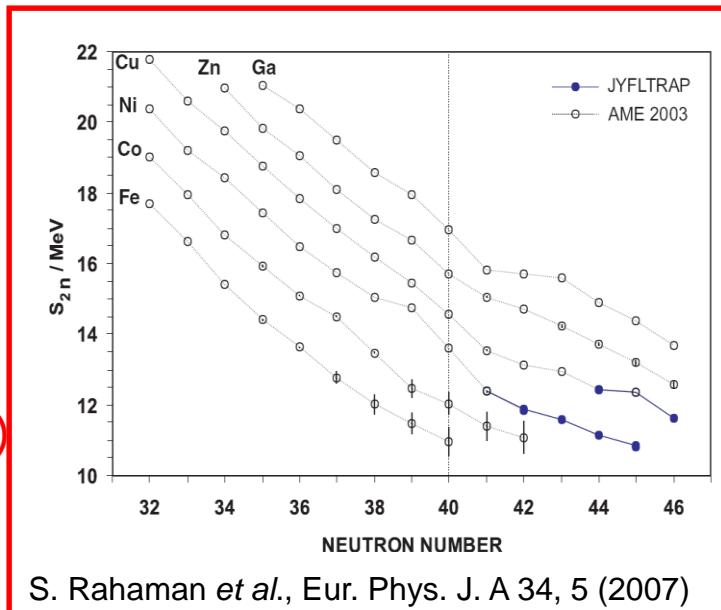

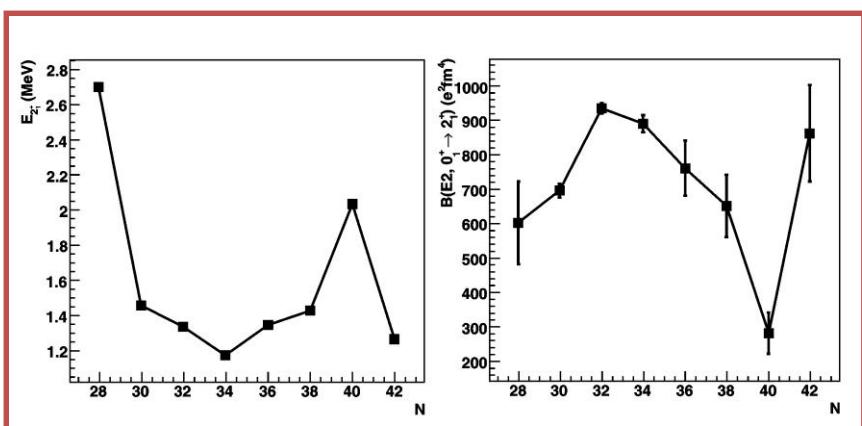

# Yields

# Physics case: $^{68}\text{Ni}$

Is the nature of the N=40 subshell closure understood?

- First excited state  $0^+$  at higher energies
- The  $2^+$  state at larger excitation energy
- Small  $B(E2, 0^+ \rightarrow 2^+)$
- No irregularity at the  $S_{2n}$  or at the binding energies
- Fragile nature of the N=40 subshell closure
- Other reasons for the small observed  $B(E2, 0^+ \rightarrow 2^+)$

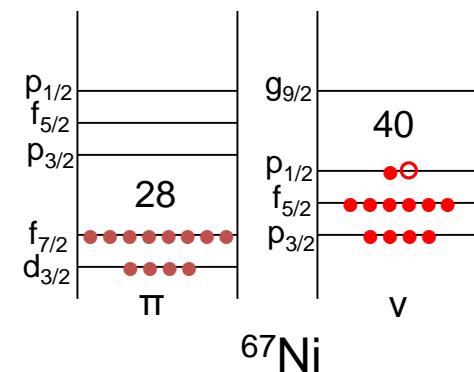

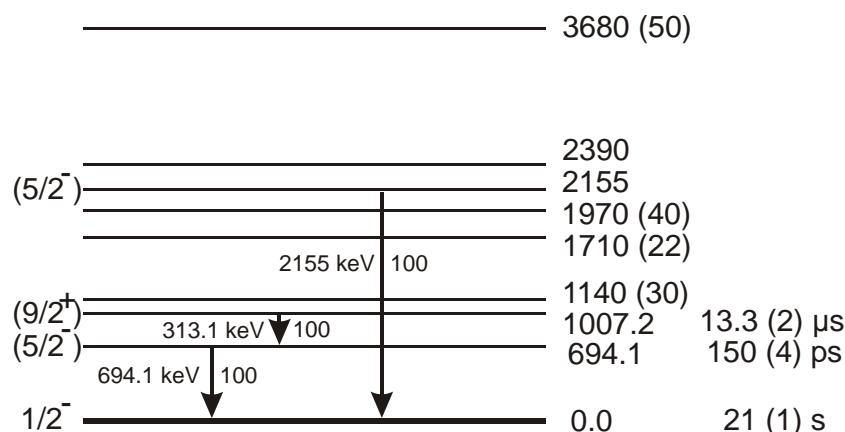

# Physics case: $^{68}\text{Ni}$

Study of the single particle character of the neutron rich Ni isotopes

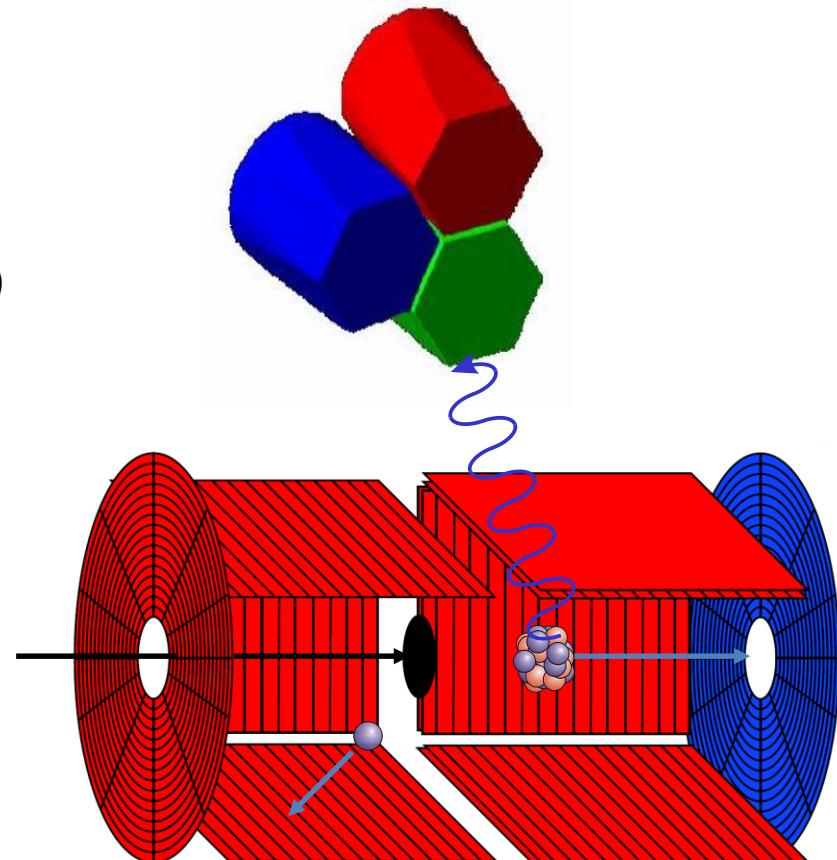

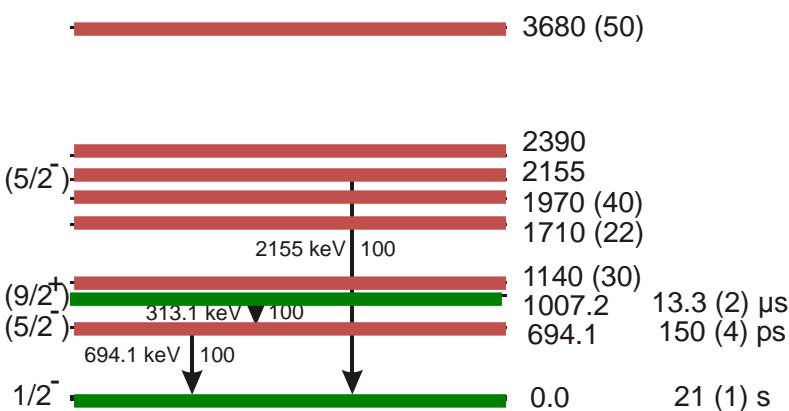

Physics case:  $^2\text{H}(^{66}\text{Ni}, \text{p})^{67}\text{Ni}$ ,  $Q = 3.583 \text{ MeV}$

- $^{67}\text{Ni}^g$  one hole state of the  $^{68}\text{Ni}$
- g factor exp. value smaller by a factor of 2 than the expected for  $1g_{9/2}$
- Unambiguous determination of the spin and parities of the the first excited states - one more state  $v_{3/2}$  not yet observed
- Single particle character of the states of  $^{67}\text{Ni}$  (relative SF's)
- A good starting point as to determine the single particle character of the Ni isotopic chain – single particle systematics

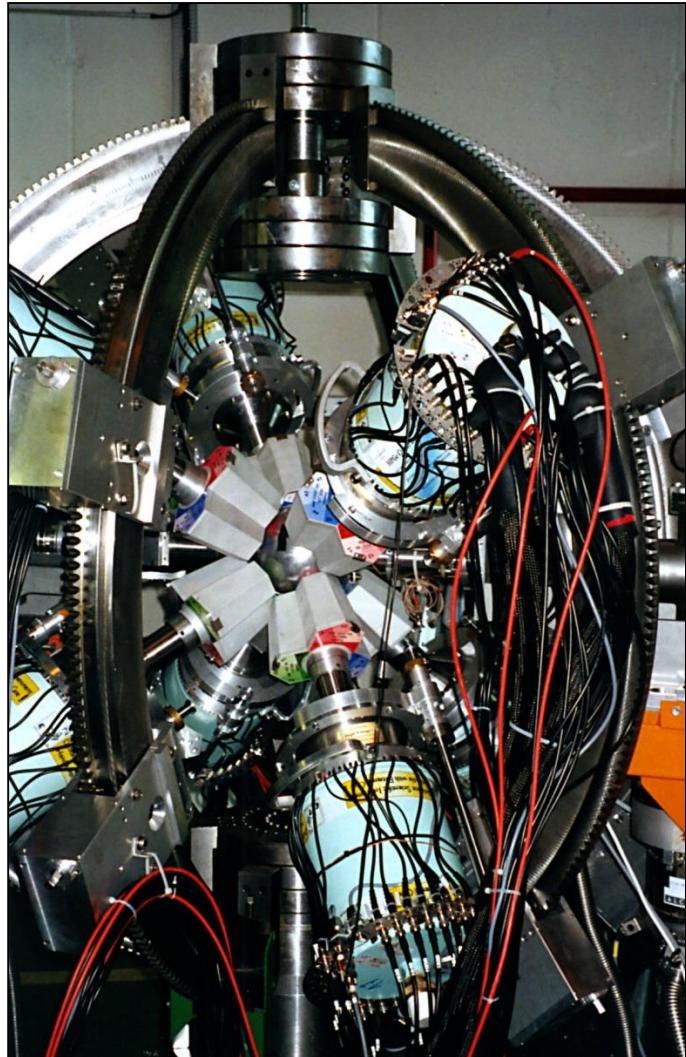

# Experimental Setup

- “Thick”  $\text{CD}_2$  target measurement ( $1\text{mgr}/\text{cm}^2$ )
  - ⊕ Spectroscopic information for the excited states up to 3 MeV.
  - ⊕ Coincidences with  $\gamma$
- “Thin”  $\text{CD}_2$  target measurement ( $100\ \mu\text{gr}/\text{cm}^2$ )
  - ⊕ Spectroscopic information for the ground and the second excited state.
  - ⊕ Singles: only backward angles

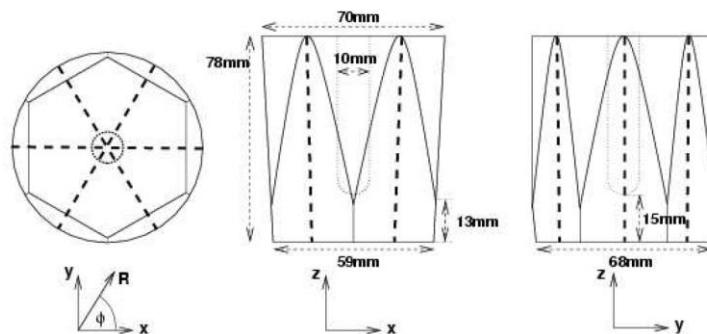

# Miniball

8 x

= 168 channels

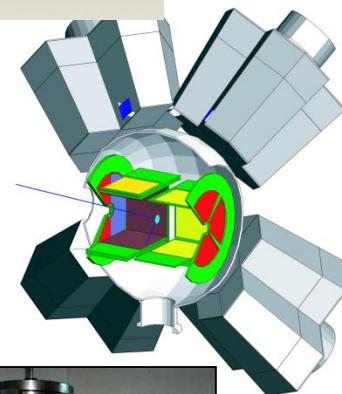

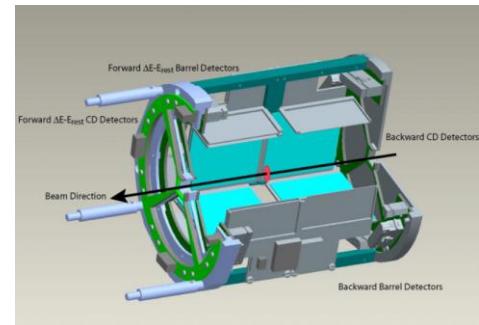

$\epsilon = 10\% @ 1 \text{ MeV}$

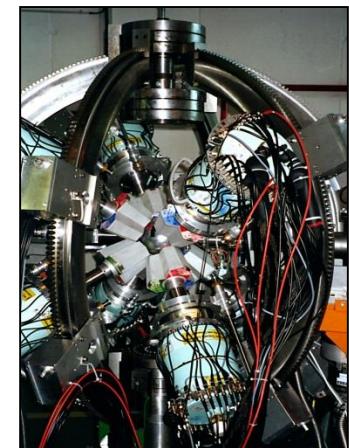

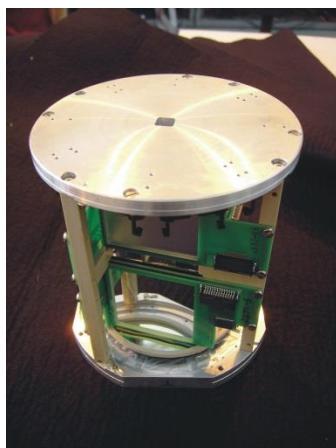

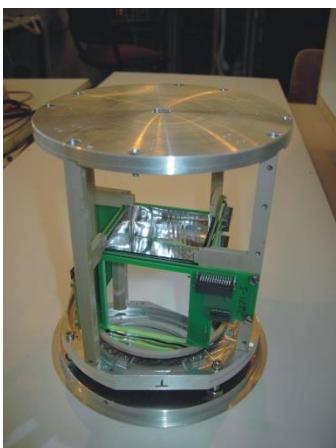

# Silicon Barrel

Detector	Angles	Thickness	Segmentation
Forw. CD ( $\Delta E$ )	8-30	300 $\mu m$	16 annular x 24 radial
Forw. CD (E)	8-30	1.5 mm	no
Forw. Barrel ( $\Delta E$ )	30-75	140 $\mu m$	16 stripes $\perp$ beam + ch. Div resistive layer
Forw. Barrel (PAD)	30-75	1 mm	no
Back. Barrel	104-152	500 $\mu m$	16 stripes $\perp$ beam + ch. Div resistive layer
Back. CD	152-172	500 $\mu m$	16 annular x 24 radial

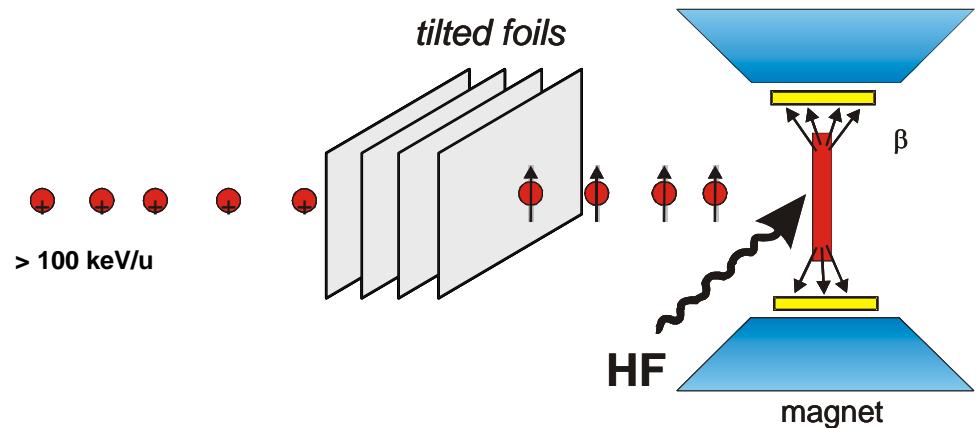

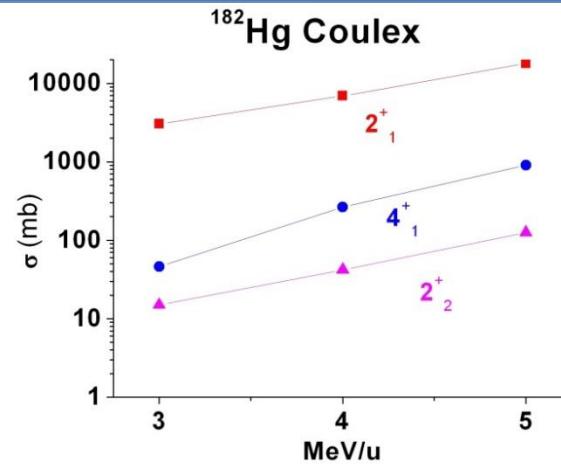

**Particle detector: 464 channels**

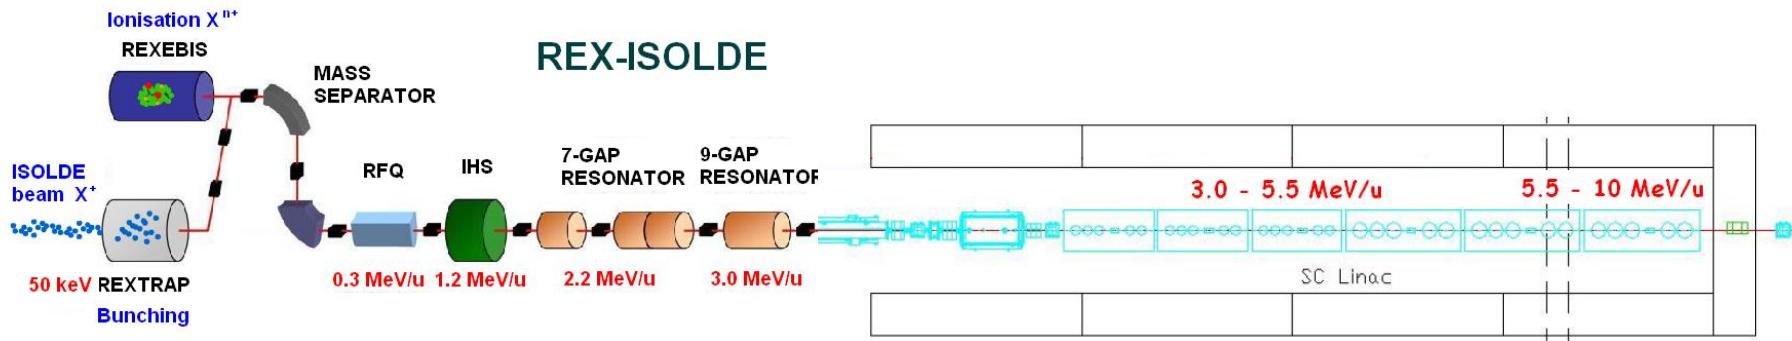

# HIE - ISOLDE

- Intensity
- Energy
  - Coulex for all RIB
  - Transfer reactions
- Efficiency low energy + accelerated
- Selectivity
- Beam “quality”
  - Reduced phase space
  - Bunching
- Polarization .....

# HIE - ISOLDE

Increase in REX energy from 3 to 10 MeV/u  
(first step an increase to 5.5 MeV/u)

**Increase proton intensity  $2 \rightarrow 6 \mu\text{A}$  (LINAC4, PSB upgrade) - target and front-end upgrade**

RFQ cooler, REX-TRAP, REX-EBIS    REX-ECR upgrades

Super-HRS for isobaric separation  
RILIS upgrade & LIST
