For more details

This is part of an ongoing project over a long time—it started more than ten years ago!—to understand the dynamics of probes of the near horizon geometry of black holes; and, hence, to understand the properties of the near horizon geometry of black holes, when the black hole microstates can be resolved.

The conceptual framework is the AdS/CFT correspondence, whose AdS₂/CFT₁ incarnation has been explicitly constructed—from both sides—for single particle probes and provides the foundation for constructing multiparticle probes and studying their chaotic dynamics.

What are Arnol'd cat map lattices?

They are lattices of Arnol'd cat maps, that are coupled between them, in a way defined by the structure of the lattice.

- ▶ What are Arnol'd cat maps?
- ▶ What does it mean that they're coupled in lattices?
- ▶ Why should we care?

What are Arnol'd cat maps?

There's just one Arnol'd cat map. It's defined by the mapping $\mathbb{R}^2 \rightarrow \mathbb{R}^2$

$$\begin{pmatrix} q \\ p \end{pmatrix}_{m+1} = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} q \\ p \end{pmatrix}_m \pmod{1}$$

It can, also, equivalently, be defined as

$$(q, p)_{m+1} = (q, p)_m \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix} \pmod{1}$$

It was invented by V. I. Arnol'd in lectures given in Paris in 1965, that were published in the book *Problèmes ergodiques de la mécanique classique* (1967), with A. Avez.

The mod 1 operation implies that, in fact, it's a mapping from the 2-torus to itself: $\mathbb{T}^2 \rightarrow \mathbb{T}^2$.

The element "2" can be, either in the lower right or the upper left corner, it doesn't matter.

Cat maps, beyond Arnol'd

Applications, from $\mathbb{T}^2 \rightarrow \mathbb{T}^2$,

$$\begin{pmatrix} q \\ p \end{pmatrix}_{m+1} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} q \\ p \end{pmatrix}_m \pmod{1}$$

with $ad - bc = 1$ and $a + d > 2$ are, now, generically, called “cat maps”.

What does it mean that they're coupled in lattices?

It means that, instead of having one map, from the 2-torus to the 2-torus, we have many maps, coupled between them—a many-body system; a field theory.

There are two ways to couple such maps:

- ▶ In phase space.
- ▶ In configuration space.

How to do so, in a particular way, that takes into account certain symmetries, that are relevant for understanding the dynamics of black holes, is the subject of this talk.

Measures of chaos

Conclusions and
outlook

Why should we care?

There are many reasons to care about the Arnol'd cat map in particular and coupling many of them, more generally.

- ▶ The Arnol'd cat map was the first system—proposed by Arnol'd in 1965—that displayed chaotic behavior in the simplest possible setting. In particular, it displayed *mixing*. It's the mod 1 that's crucial for ensuring mixing.
- ▶ Many more applications in information theory most recently (steganography) as well as in fluid mechanics.
- ▶ It can be understood as describing an harmonic oscillator in an inverted potential, whose runaway behavior is cured by the periodic boundary conditions; which implies that chaotic systems can be imagined as Hamiltonian systems this way.
- ▶ It describes an accelerated observer in the near horizon geometry of an extremal black hole.
- ▶ Its dynamical properties can be used to describe the properties of the near horizon geometry itself.

A lattice approach to holographic systems

The idea is to set up a lattice on the phase space of the system of interest—but in a way that preserves the isometries of the space and to use group elements to represent the dynamics. The scaling limit is a much more delicate issue. In previous work we studied compact phase spaces, namely tori; now we have extended the approach to non-compact phase spaces. We've focused on the single-sheet hyperboloid, that describes the AdS_2 manifold, because it describes the radial and temporal part of the near horizon geometry of extremal black holes, that factorizes from the charge manifold.

A modular lattice: the links

The way for going from one point to another is by the Weyl map-mod N :

$$X_{n+1} = AX_nA^{-1} = A^nX_0A^{-n} \text{ mod } N$$

with $A \in SL(2, \mathbb{Z}_N)/SO(1, 1, \mathbb{Z}_N)$.

The elementary transformations are translations along the two light cone generators, L and R

$$L = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \quad R = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix}$$

These, also, generate the braid group. Their products describe more complicated motion. In particular, the product LR^{-1} is the Arnol'd cat map. And any $A \in SL_2[\mathbb{Z}]$ of interest can be written as a product of the L's and the R's and their inverses.

Why is this approach relevant for black holes? And why is it useful?

The reason this approach is relevant for describing properties of black holes is that $N \propto e^{S_{\text{BH}}}$, the dimension of the space of microstates of the black hole, that are resolved, when the probe is a quantum object. Therefore the dynamics of the probe can be described using unitary operators, that act on this space of states, that is finite-dimensional.

The reason this approach is useful is because this approach preserves a form of the isometries of AdS_2 in a way that is consistent

The scaling limit requires two cutoffs

In fact a proper analysis requires two cutoffs—as might be expected: A long–distance (IR) cutoff and a short–distance (UV) cutoff.

The single–sheet hyperboloid is defined by the equation

$$x^2 + y^2 - z^2 = R_{\text{AdS}}^2$$

We enclose (part of it!) in a cube of size $L \equiv aN$. This defines the IR cutoff L and the UV cutoff a .

We write

$$R_{\text{AdS}} \equiv Ma$$

If we set $x = ka$, $y = la$ and $z = ma$, with $k, l, m \in \mathbb{Z}$, we find

$$k^2 + l^2 - m^2 = M^2$$

The scaling limit requires two cutoffs

We can show that (a) it is possible to take the combined limits $a \rightarrow 0$ and $L \rightarrow \infty$, with $R_{\text{AdS}} = \text{fixed}$ and recover the smooth geometry and (b) for fixed L and a we can impose periodic boundary conditions on the cube, of size L , that encloses the hyperboloid. This property is expressed by the relation

$$k^2 + l^2 - m^2 = M^2 \bmod N$$

In the paper [arXiv:1908.06641](https://arxiv.org/abs/1908.06641) we show how to construct sequences of integers, (M_n, N_n) , $n = 1, 2, \dots$, with the properties

- ▶ $N_n > M_n$
- ▶ $M_n^2 \equiv 1 \bmod N_n$
- ▶ $1 < \lim_{n \rightarrow \infty} N_n/M_n = L/R_{\text{AdS}}$. We can send $L \rightarrow \infty$, keeping $R_{\text{AdS}} = \text{fixed}$. The radii thus constructed are related to the so-called k -Fibonacci sequences; the limit $L \rightarrow \infty$ can be taken as $k \rightarrow \infty$.

It is an open problem to generalize the construction for any value of R_{AdS} .

The symmetry in phase space: Covariance under symplectic transformations

The single Arnol'd cat map is an element of $SL_2[\mathbb{Z}]$. This is the group of all 2×2 integer-valued matrices, with determinant 1.

This, also, means that it is an element of $Sp_2[\mathbb{Z}]$, since

$$J = M^T J M$$

where

$$J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$$

and M is the Arnol'd cat map. (This property holds for any element of $SL_2[\mathbb{Z}]$; that is, thus, also, an element of $Sp_2[\mathbb{Z}]$.)

This identification no longer holds for more than one map:

It's *not* true that an element of $SL_{2n}[\mathbb{Z}]$ is, also, an element of $Sp_{2n}[\mathbb{Z}]$.

What could be the guiding principle for constructing elements of $Sp_{2n}[\mathbb{Z}]$, that we can identify as coupled Arnol'd cat maps?

Conclusions and outlook

The relation between the Arnol'd cat map and the Fibonacci sequence

The key observation is that the Arnol'd cat map is related in a very special way to the Fibonacci sequence, defined by the recursion relation

$$f_{n+1} = f_n + f_{n-1}$$

with $f_0 = 0, f_1 = 1$. (For other initial conditions, the integers, generated by this sequence, are known as the “Lucas numbers”.)

The reason is that the Fibonacci sequence can be written in matrix form as

$$\begin{pmatrix} f_n \\ f_{n+1} \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} f_{n-1} \\ f_n \end{pmatrix} \equiv \mathcal{A} \begin{pmatrix} f_{n-1} \\ f_n \end{pmatrix}$$

The relation between the Arnol'd cat map and the Fibonacci sequence

We note that $\det \mathcal{A} = -1$; \mathcal{A} satisfies the relation

$$\mathcal{A}^T \mathcal{J} \mathcal{A} = -\mathcal{J}$$

while

$$\mathcal{A}^2 = \mathcal{M}$$

the Arnol'd cat map, introduced previously– which implies that $\mathcal{M} \in \text{Sp}_2[\mathbb{Z}]$:

$$\mathcal{M}^T \mathcal{J} \mathcal{M} = \mathcal{J}$$

Conclusions and outlook

The relation between the Arnol'd cat map and the Fibonacci sequence

Furthermore, we can prove, by induction, that

$$M^n = \mathcal{A}^{2n} = \begin{pmatrix} f_{2n-1} & f_{2n} \\ f_{2n} & f_{2n+1} \end{pmatrix}$$

These properties mean that anything we can describe using the Arnol'd cat map, we can describe using the Fibonacci sequence and vice versa.

This implies, in particular, that we can describe the coupling between Arnol'd cat maps as the coupling between Fibonacci sequences!

Coupling Fibonacci sequences consistent with symplectic covariance

This can be achieved as follows: Write

$$\begin{aligned}f_{m+1} &= a_1 f_m + b_1 f_{m-1} + c_1 g_m + d_1 g_{m-1} \\g_{m+1} &= a_2 g_m + b_2 g_{m-1} + c_2 f_m + d_2 f_{m-1}\end{aligned}$$

where the a_i, b_i, c_i, d_i are integers, $f_0 = 0 = g_0$ and $f_1 = 1 = g_1$ are the initial conditions and $m = 1, 2, 3, \dots$

We wish to understand what constraints symplectic covariance imposes.

which implies

$$D = I_{n \times n} \quad C = C^T$$

Therefore $a_1 = k_1$, $a_2 = k_2$, $c_1 = c_2 = c$. In terms of these parameters, the recursion relations take the form

$$\begin{aligned} f_{m+1} &= k_1 f_m + f_{m-1} + c g_m \\ g_{m+1} &= k_2 g_m + g_{m-1} + c f_m \end{aligned}$$

Coupling Fibonacci sequences consistent with symplectic covariance: The k -Fibonacci sequence

This, in turn, can be identified as describing a particular coupling between a k_1 - and a k_2 -Fibonacci sequence. The k -Fibonacci sequence is the generalization of the Fibonacci sequence, defined by the relation

$$f_{n+1} = kf_n + f_{n-1}$$

where k is an integer.

Coupling Fibonacci sequences consistent with symplectic covariance

This particular coupling is determined by the condition that the square of the evolution matrix is an element of $\text{Sp}_4[\mathbb{Z}]$:

$$\mathcal{A}^{(2)} = \begin{pmatrix} 0 & 1 \\ 1 & C \end{pmatrix} \Rightarrow M = \mathcal{A}^{(2)2} = \begin{pmatrix} 1 & C \\ C & 1 + C^2 \end{pmatrix} \quad (2)$$

The role of the coupling is played by the integer c .

We remark that, if $c = 0$ and $k_1 = k_2 = 1$, we recover two, decoupled, Arnol'd cat maps; if $c \neq 0$, and $k_1 = k_2 = 1$ we can, thereby, identify two “coupled” Arnol'd cat maps, while, if $k_1 = k_2 = k$, the system decouples into two, independent, $(k + c)$, resp. $(k - c)$ -cat maps, for $f_m \pm g_m$.

Coupling Fibonacci sequences consistent with symplectic covariance

Now we can define the coupling matrix for n sequences as

$$C = K + PG + GP^T$$

where K and G are diagonal matrices and P is the “shift” operator:

$$P = \begin{pmatrix} 0 & 0 & \cdots & 1 \\ 1 & 0 & \cdots & 0 \\ 0 & 1 & \cdot & 0 \\ \cdots & \cdots & \cdots & \cdots \\ 0 & \cdots & 1 & 0 \end{pmatrix}$$

The corresponding $2n \times 2n$ evolution matrix, $\mathcal{A}^{(n)}$ is given by

$$\mathcal{A}^{(n)} = \begin{pmatrix} 0_{n \times n} & I_{n \times n} \\ I_{n \times n} & C \end{pmatrix}$$

Coupling Fibonacci sequences consistent with symplectic covariance

and satisfies the relation $\mathcal{A}^{(n)\text{T}} \mathbf{J} \mathcal{A}^{(n)} = -\mathbf{J}$.

Its square,

$$\mathbf{M} = \mathcal{A}^{(n)2} = \begin{pmatrix} I_{n \times n} & \mathbf{C} \\ \mathbf{C} & I_{n \times n} + \mathbf{C}^2 \end{pmatrix}$$

therefore satisfies the relation $\mathbf{M}^{\text{T}} \mathbf{J} \mathbf{M} = \mathbf{J}$, showing that $\mathbf{M} \in \text{Sp}_{2n}[\mathbb{Z}]$. Since $\mathcal{A}^{(n)}$ is symmetric (from the property that $\mathbf{C} = \mathbf{C}^{\text{T}}$), \mathbf{M} is positive definite and the eigenvalues, $\lambda \neq 1$, come in pairs, $(\lambda, 1/\lambda)$, with $\lambda > 1$. This property implies that, for all matrices \mathbf{K} and \mathbf{G} , this system of coupled maps is hyperbolic.

Measures of chaos

Conclusions and
outlook

Coupling Fibonacci sequences consistent with symplectic covariance

It is possible to decompose the classical evolution matrix M in terms of the generators of the symplectic group

$$M = \begin{pmatrix} I_{n \times n} & 0_{n \times n} \\ C & I_{n \times n} \end{pmatrix} \begin{pmatrix} I_{n \times n} & C \\ 0_{n \times n} & I_{n \times n} \end{pmatrix}$$

Moreover each factor generates, for any symmetric, integer, matrix C , an abelian subgroup of $\text{Sp}_{2n}[\mathbb{Z}]$. These factors are called “left” (resp. “right”) translations.

An important special case arises if we impose translation invariance along the chain, i.e. $K_l = K$ and $G_l = G$ for all $l = 1, 2, \dots, n$.

Periodic behavior

Since the entries of M are integers, it acts in a particular way on rational points. A particularly interesting class of such points is defined by

$$\mathbf{x}_0 = (k_1/N, k_2/N, \dots, k_n/N, l_1/N, l_2/N, \dots, l_n/N)$$

where $0 \leq k_l \leq N, 0 \leq l_l \leq N$ and k_l, l_l, N integers.

On such points the map

$$(\mathbf{k}/N, \mathbf{l}/N)_{m+1} = (\mathbf{k}/N, \mathbf{k}/N)_m M \bmod 1$$

takes the form

$$(\mathbf{k}, \mathbf{l})_{m+1} = (\mathbf{k}, \mathbf{l})_m M \bmod N$$

The points $\{(\mathbf{k}, \mathbf{l})\}$ belong to the $2n$ -torus, $\mathbb{T}^{2n}[N]$.

The matrix $M \bmod N \in \text{Sp}_{2n}[\mathbb{Z}_N]$ and has period $T(N)$, where $T(N)$ is defined as the smallest integer such that

$$M^{T(N)} \equiv I_{n \times n} \bmod N$$

The issue of the periods $T(N)$

The period, $T(N)$ controls the “mixing” properties of the map. So it is useful to know how it scales with N . What is fascinating is that it seems to be a “random” function of N ,

Figure: Period $T(N)$ for $N = p_{11}$ (the eleventh prime) to p_{31} , (the thirty-first prime) for $l = 1$, $n = 1$ and 2. We remark the dramatic change from $n = 1$, one map, to $n = 2$, two coupled maps. This reflects the dramatic increase in size of the order of the group.

The issue of the periods, $T(N)$

What is interesting is that, even for large N , the period $T(N)$ can be much smaller than N . Indeed, for the single Arnol'd cat map, Falk and Dyson showed (1982) that, when $N = f_q$, a Fibonacci number, that's a prime, then $T(N = f_q) = 2q$. This means very *fast* mixing, since $q \approx \log f_q$.

The period for coupled Arnol'd cat maps

The key observations:

$$\mathcal{A}^{(n)} = \begin{pmatrix} 0 & I \\ I & C \end{pmatrix} \Rightarrow M = [\mathcal{A}^{(n)}]^2 = \begin{pmatrix} I & C \\ C & I + C^2 \end{pmatrix}$$

$$M^m = \begin{pmatrix} C_{2m-1} & C_{2m} \\ C_{2m} & C_{2m+1} \end{pmatrix}$$

- ▶ The sequence of matrices C_m , is defined by the matrix C , the initial conditions $C_0 = 0_{n \times n}$, $C_1 = I_{n \times n}$ and the recursion relation

$$C_{m+1} = CC_m + C_{m-1}$$

The period for coupled Arnol'd cat maps

Therefore the period, $T(N)$, is determined by the relations $C_{2T(N)} \equiv 0 \pmod N$, $C_{2T(N)-1} \equiv I_{n \times n} \pmod N$ and $C_{2T(N)+1} = C \cdot C_{2T(N)} + C_{2T(N)-1} \equiv I_{n \times n} \pmod N$. The C_m are matrices, that are *matrix polynomials* in the matrix C ; in fact they are the Fibonacci polynomials, defined by

$$F_{m+1}(x) = xF_m(x) + F_{m-1}(x)$$

with initial conditions, $F_0(x) = 0$ and $F_1(x) = 1$, when the argument is a matrix!

Using these, instead of the evolution operator M , is more efficient, since C and the Fibonacci polynomials constructed from it, has half the size of M .

Locality in configuration space

Locality isn't an obvious property in phase space—it is much clearer what it means in configuration space, where the dynamical equations are those of Newton, rather than those of Hamilton. Straightforward calculation implies that these take the form

$$\mathbf{q}_{m+1} - 2\mathbf{q}_m + \mathbf{q}_{m-1} = \mathbf{q}_m C^2 \bmod N$$

These describe *inverted* harmonic oscillators—but whose “runaway” behavior is “cured” by the periodic boundary conditions!

Measures of chaos: Lyapunov exponents

The Arnol'd cat map (as well as the many-body systems obtained by coupling many of these maps in the way presented above) is a chaotic system. This property can be highlighted by computing the spectrum of the Lyapunov exponents, available in closed form

$$\lambda_{\pm, l} = \log \rho_{\pm, l} = \log \left\{ \frac{2 + D_l^2}{2} \pm \frac{|D_l|}{2} \sqrt{D_l^2 + 4} \right\}$$

where

$$D_J = K + 2 \sum_{l=1}^{\lfloor \frac{n-1}{2} \rfloor} \left(G_l \cos \frac{2\pi l J}{n} \right)$$

Measures of chaos: Lyapunov exponents

The Lyapunov exponents describe the evolution in phase space, so, in the present case, they're the eigenvalues of M . They can be computed from the equations of motion, in *configuration* space, as follows:

$$\mathbf{q}_{m+1} - 2\mathbf{q}_m + \mathbf{q}_{m-1} = \mathbf{q}_m C^2$$

by diagonalizing C :

$$F^\dagger C F \equiv D$$

using the discrete Fourier transform

$$F_{IJ} = e^{2\pi i IJ/n} / \sqrt{n} \equiv \omega_n^{IJ} / \sqrt{n}$$

and writing

$$\mathbf{q}_m \equiv \mathbf{r}_m F$$

(assuming periodic boundary conditions)

Measures of chaos: Lyapunov exponents

The r_m satisfy the equation(s)

$$r_{m+1} - 2r_m + r_{m-1} = r_m D^2$$

where

$$D_{IJ} = \delta_{IJ} D_J = \delta_{IJ} \left(K + 2G \cos \frac{2\pi J}{n} \right)$$

for the case of nearest-neighbor interactions. We note here that, if n is even, then the mode $J_0 = n/2$ has zero eigenvalue, when $K = 2G$. If n is odd, on the other hand, a zeromode cannot exist, because K and G are positive integers.

It is possible to include the case of couplings beyond nearest-neighbors, i.e. G_l , with $1 < l \leq (n-1)/2$, as follows:

$$D_J = K + 2 \sum_{l=1}^{\frac{n-1}{2}} \left(G_l \cos \frac{2\pi l J}{n} \right)$$

Measures of chaos: Lyapunov exponents

We now set

$$(\mathbf{r}_m)_I = r_{I,m} \equiv \delta_{IJ} \rho_I^m a_J$$

(where $I, J = 1, 2, \dots, n$). We duly find a quadratic equation for ρ_I :

$$\rho_I^2 - (2 + D_I^2)\rho_I + 1 = 0 \Leftrightarrow \rho_{\pm, I} = \frac{2 + D_I^2}{2} \pm \frac{|D_I|}{2} \sqrt{D_I^2 + 4}$$

Therefore

$$\rho_{\pm, I} = e^{\log \lambda_{\pm, I}}$$

Measures of chaos: The Kolmogorov-Sinai entropy

The Kolmogorov-Sinai entropy is, in fact, a *rate of change* of entropy. It is defined as the sum of the *positive* Lyapunov exponents

$$S_{\text{KKS}} = \sum_{l=0}^{n-1} \lambda_{+,l}$$

and is expected to scale as the volume of the system:

Measures of chaos

The reason it is useful, is that, by dimensional analysis, $1/S_{K-S}$ has the dimensions of time—so it is expected that the mixing time should be proportional to $1/S_{K-S}$; the only question being what is the proportionality constant. This isn't a trivial issue and, in general, we would expect that mixing is faster, the greater the K-S entropy, but there are known counterexamples depending on the choice of the initial probability distribution. So there are considerable conceptual issues yet to resolve.

For black holes and quantum many-body systems, it has been conjectured that the mixing time is the scrambling time and these, in turn, are described by $1/S_{K-S}$. What the proportionality coefficient is, remains to be found.

Conclusions and outlook

Conclusions and outlook

- ▶ How to couple Arnol'd cat maps isn't a well-defined statement, unless we specify what the symmetries are supposed to be. In this work we have shown how to couple n Arnol'd cat maps (as well as their generalizations), under the assumption that the evolution operator for the n maps is an element of $\text{Sp}_{2n}[\mathbb{Z}]$ and showed how locality can be tuned for such systems.

The rule is the following: The evolution operator, M , of n cat maps, that is an element of $\text{Sp}_{2n}[\mathbb{Z}]$, is given by the expression

$$M = \begin{pmatrix} I_{n \times n} & C \\ C & I_{n \times n} + C^2 \end{pmatrix}$$

where C is an $n \times n$ symmetric matrix, that takes integer values. If the operations are done mod N , then the system has fascinating features.

Conclusions and outlook

- ▶ This construction is particularly appropriate for addressing the dynamics of n -body chaotic systems, that do not have an integrable limit. Nevertheless everything is under analytical control.
- ▶ They do show non-trivial conservation laws, that deserve closer scrutiny.
- ▶ This is, also, relevant for constructing toy models of the near horizon geometry itself of extremal black holes. They, already, pass, certain, non-trivial checks.

Conclusions and
outlook

Conclusions and outlook

- ▶ These systems are classical; their quantum dynamics requires generalizing the construction for the single Arnol'd cat map, that describes single-particle probes of a fixed geometry.
- ▶ Such a generalization can, on the one hand, describe multi-particle probes of the near horizon geometry; but it can, also, be used to describe the fluctuations of the near horizon geometry itself.
- ▶ Their application to information processing has a broader range of applicability to (quantum) computing problems.
- ▶ These are lattice field theories, so their scaling limits are of particular interest, also!
- ▶ *The best is yet to come!*
