(In)dependence of various LFV observables in the non-minimal SUSY

Monday 14 January 2019 17:50 (20 minutes)

We investigate the muon anomalous magnetic moment, the $\mu \rightarrow e\gamma$ branching ratio and the $\mu \rightarrow e$ conversion rate in the nuclei from the point of view of the planned $\mu \rightarrow e$ conversion experiments. In the MSSM these processes are strongly correlated through tan β enhanced contributions. We demonstrate how in the Minimal R-symmetric Supersymmetric Standard Model the $\mu \rightarrow e\gamma$ branching ratio and the $\mu \rightarrow e$ conversion rate in the nuclei give distinct bounds on the parameter space. We also consider the supersymmetric contributions to the muon anomalous magnetic moment, generated by a subset of topologies contributing to the LFV observables. We briefly discuss the generic implementation of the aforementioned observables into the FlexibleSUSY spectrum-generator generator. Looking at the current $\mu \rightarrow e\gamma$ searches, the analysis points to the need of constructing a dedicated $\mu \rightarrow e$ conversion experiment to cover as large parameter space as possible in the non-minimal supersymmetric models.
