

## Mass load of magnetically-dominated jets

*Monday 7 September 2020 09:30 (30 minutes)*

Relativistic jets in active galactic nuclei start as a Poynting flux produced in the ergosphere of rapidly rotating black holes. However, at distances of a few tens of gravitational radii from the black hole these jets produce synchrotron and inverse Compton radiation, a clear indication that they have a significant content of charged particles. In this talk I discuss the origin of such particles with emphasis on the role played by the hot accretion flows in the process of jet generation.
