Perturbations
constraints

Conclusions

Since the '90s and the discovery of the late accelerated expansion of the Universe, the standard cosmological model has been the most efficient in describing our observations.

This model relies on a Cold Dark Matter component to describe the evolution of cosmic structures and on a cosmological constant Λ to account for the accelerated expansion phase.

The Λ CDM gives predictions for cosmological observables in terms of 6 standard parameters

$$\{\Omega_b, \Omega_{cdm}, n_s, A_s, H_0, \tau\}$$

The Cosmic Microwave Background

CMB

Beyond the
 Λ CDM model

Background
Constraints
Perturbations
constraints

Conclusions

The minimal Λ CDM model explains quite efficiently cosmological observables, including the most primordial available: the Cosmic Microwave Background

This relic radiation from the Big Bang carries information on the density distribution and the primordial phases of the Universe

Observing the
CMB

Beyond the
 Λ CDM model

Background
Constraints
Perturbations
constraints

Conclusions

CMB photons travel through the more recent Universe and are therefore affected also by more recent physical mechanisms, e.g. CMB lensing and ISW effect.

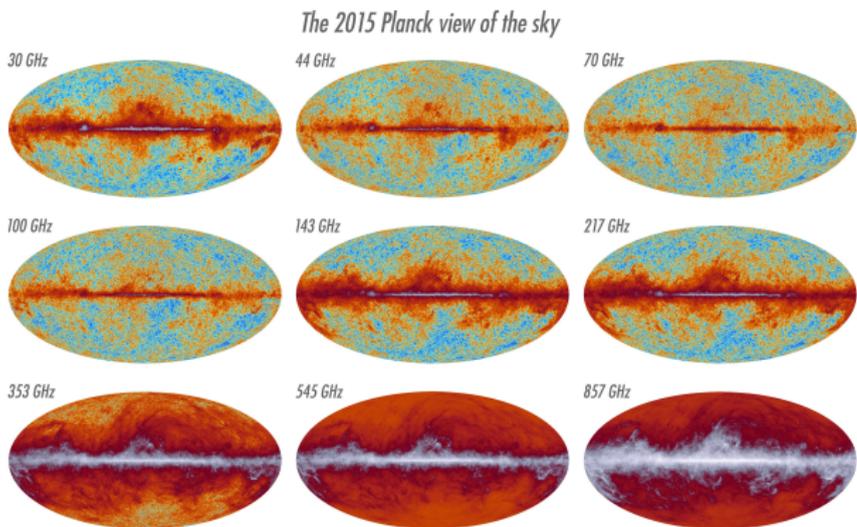

CMB photons contain also informations on the more recent phases of the Universe and can be used to test cosmological models on a wide time range.

The Planck Satellite

Early in 2015, the ESA Planck satellite released the most up to date CMB data.

Accurate foreground control and extreme sensitivity.

Observing the
CMB

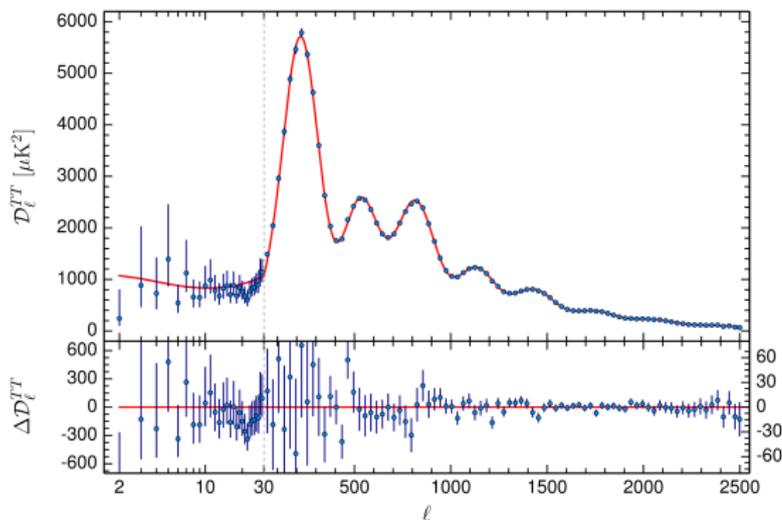

Beyond the
 Λ CDM model

Background
Constraints
Perturbations
constraints

Conclusions

Λ CDM is a good fit to CMB data and within this framework accurate constraints on cosmological parameters can be obtained.

CMB allows to test the assumption of a Cosmological Constant (Λ) as the responsible for the late time acceleration.

Abandoning this paradigm impacts the evolution of the Universe through changes of

- background expansion
- evolution of cosmological perturbations

CMB power spectra are affected by these modifications

What to test for?

If we want to test Λ we have to describe departures from it:

- parametrized deviations
find peculiar properties of your model and parametrise them (e.g. $w(z) = -1$)
- specific alternative models
assume a specific model and test whether or not it better fits the data

Conclusions

What to test for?

If we want to test Λ we have to describe departures from it:

- parametrized deviations
find peculiar properties of your model and parametrise them (e.g. $w(z) = -1$)
- specific alternative models
assume a specific model and test whether or not it better fits the data

Both approaches can be applied to the two broad classes of alternatives to Λ

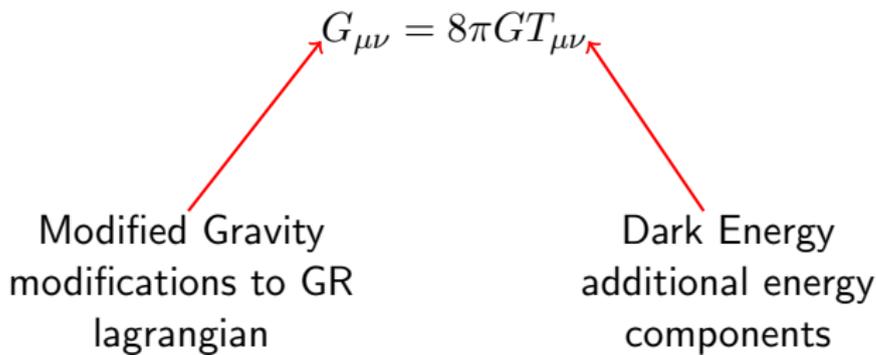

$$G_{\mu\nu} = 8\pi GT_{\mu\nu}$$

What to test for?

If we want to test Λ we have to describe departures from it:

Data combinations

These parametrizations are investigated combining Planck with additional observations

- **Planck baseline:** Planck TT + low- ℓ polarization
- **background probes:**
 - BAO: SDSS (Ross et al 2014), BOSS (Anderson et al. 2014), 6dFGS (Beutler et al. 2011)
 - SN: JLA (Betoule et al. 2013)
 - H_0 conservative prior (Efstathiou 2014)
- **perturbation probes:**
 - RSD (BOSS DR11, Samushia et al. 2014)
 - WL (CFHTLenS, Kilbinger et al. 2013, Heymans et al. 2013), with an ultra conservative cut of non linear scales

Equation of State

Assuming the background expansion deviates from the standard Λ CDM, the EoS parameter can depart from the constant -1

Dark Energy
and Modified
Gravity

Matteo
Martinelli

Observing the
CMB

Beyond the
 Λ CDM model

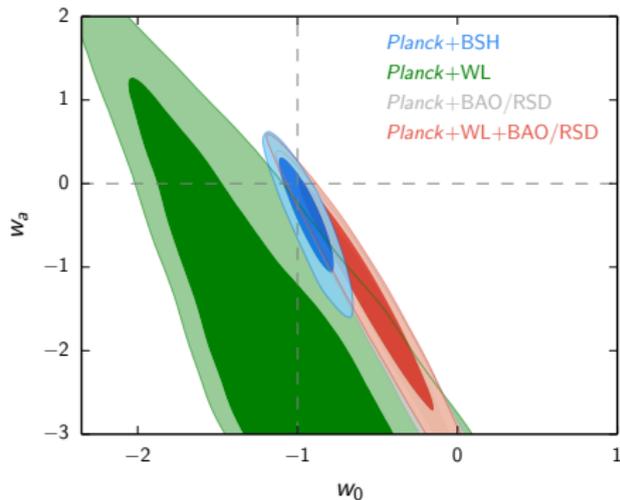

Background
Constraints

Perturbations
constraints

Conclusions

Top-down approach

- Λ CDM limit in agreement with all data combinations
- possible hint of tensions between the datasets

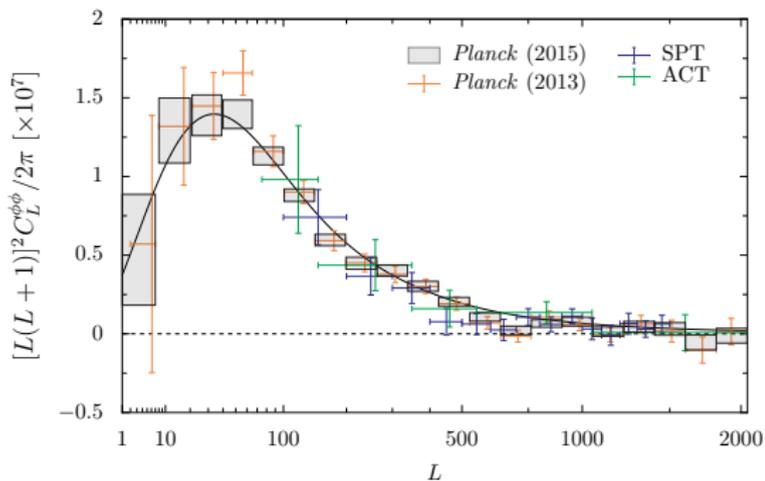

Bottom-up approach

- Mild tension with Λ CDM ($\approx 2\sigma$)
- Tension enhanced including perturbation probes (RSD and WL)

Lensing reconstruction

From Planck CMB maps it's possible to reconstruct the CMB lensing potential power spectrum through quadratic estimators

Planck 2015 results. XV. Gravitational lensing

Planck 2015
results on
Dark Energy
and Modified
Gravity

Matteo
Martinelli

Observing the
CMB

Beyond the
 Λ CDM model

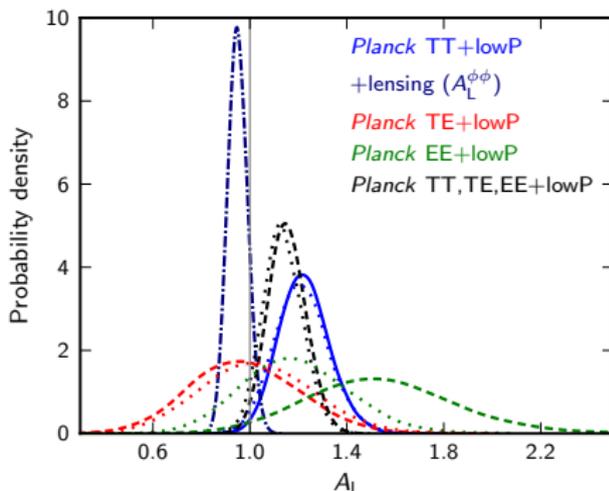

Background
Constraints

Perturbations
constraints

Conclusions

The amplitude of lensing potential

Planck collaboration measured how much the amplitude of the CMB lensing potential power spectrum deviates from the Λ CDM prediction ($C_\ell = A_L C_\ell^{\Lambda\text{CDM}}$), both through temperature and polarization spectra and through the extraction of the lensing potential from CMB maps.

Planck 2015
results on
Dark Energy
and Modified
Gravity

Matteo
Martinelli

Observing the
CMB

Beyond the
 Λ CDM model

Background
Constraints

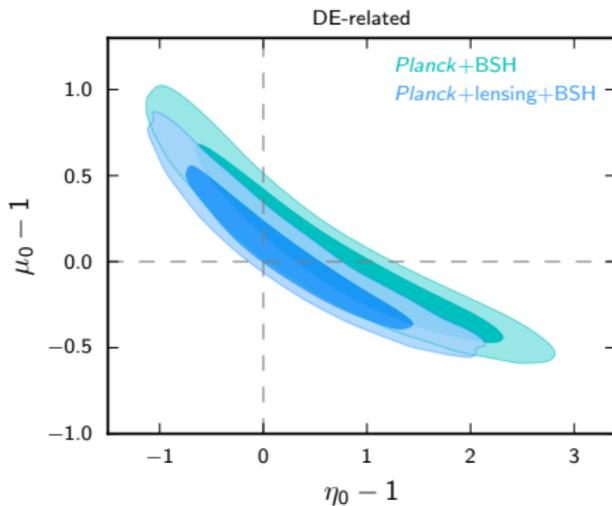

Perturbations
constraints

Conclusions

The importance of being lensed

Results obtained from lensing extraction seem “more in agreement” with Λ CDM.

This feature affects significantly the slight tension with the standard model found with the MGCAMB approach

1 Observing the CMB

2 Beyond the Λ CDM model

- Background Constraints
- Perturbations constraints

Conclusions

Planck 2015
results on
Dark Energy
and Modified
Gravity

Matteo
Martinelli

Observing the
CMB

Beyond the
 Λ CDM model

Background
Constraints
Perturbations
constraints

Conclusions

- Overall agreement between Planck and the Λ CDM model
- “Agnostic” analysis, based on several parametrizations and approaches
- Improvement of previous bounds on both background and perturbation parametrizations
- Planck+external datasets results show some marginal tensions with Λ CDM

EoS PCA

Planck 2015
results on
Dark Energy
and Modified
Gravity

Matteo
Martinelli

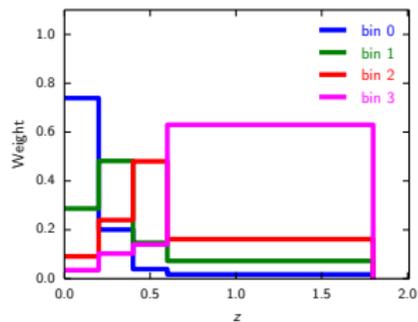

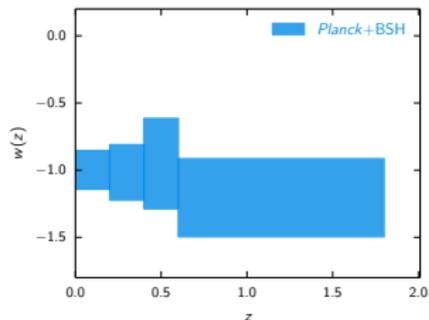

Observing the
CMB

Beyond the
 Λ CDM model

Background
Constraints
Perturbations
constraints

Conclusions

The PCA approach allows to avoid any assumptions on the behaviour of the EoS. The value of $w(z)$ is free to vary in different redshift bins. Model independent, but larger errors.

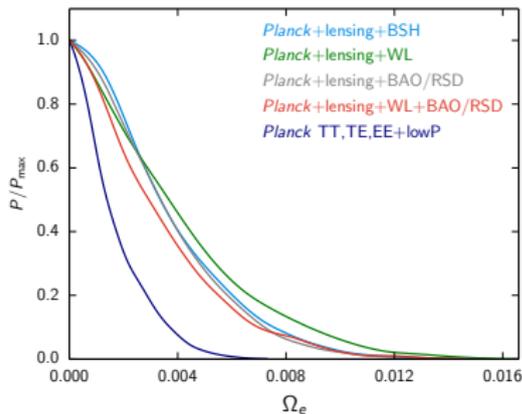

Planck 2015 results. XIV. Dark energy and modified gravity

Early Dark Energy

This kind of models account for a time evolving DE with non vanishing density at early times

$$\Omega_{de}(a) = \frac{\Omega_{de}^0 - \Omega_e(1 - a^{-3w_0})}{\Omega_{de}^0 + \Omega_m^0 a^{3w_0}} + \Omega_e(1 - a^{-3w_0})$$

Effective Field Theory for DE/MG

In general there are 9 functions of time that include majority of Modified Gravity models

$$\begin{aligned} S = \int d^4x \sqrt{-g} & \left\{ \frac{m_0^2}{2} [1 + \Omega(\tau)] R + \Lambda(\tau) - a^2 c(\tau) \delta g^{00} \right. \\ & + \frac{M_2^4(\tau)}{2} (a^2 \delta g^{00})^2 - \bar{M}_1^3(\tau) 2a^2 \delta g^{00} \delta K_\mu^\mu \\ & - \frac{\bar{M}_2^2(\tau)}{2} (\delta K_\mu^\mu)^2 - \frac{\bar{M}_3^2(\tau)}{2} \delta K_\nu^\mu \delta K_\mu^\nu + \frac{a^2 \hat{M}^2(\tau)}{2} \delta g^{00} \delta R^{(3)} \\ & \left. + m_2^2(\tau) (g^{\mu\nu} + n^\mu n^\nu) \partial_\mu (a^2 g^{00}) \partial_\nu (a^2 g^{00}) \right\} + S_m[\chi_i, g_{\mu\nu}] \end{aligned}$$

Describes scalar tensor theories with one extra dynamical d.o.f.
