Revisiting butterfy effects for asymptotically Lifshitz black hole

Friday 14 March 2025 10:50 (20 minutes)

We explore connections between two salient chaotic

features, namely Lyapunov exponent and butterfly velocity, for the class of asymptotically Lifshitz black hole background with arbitrary critical exponent by implementing three different holographic approaches, namely, entanglement wedge method, out of time-ordered correlators (OTOC) and pole-skipping. We present a comparative study where all of the above methods yield exactly similar results for the butterfly velocity and Lyapunov exponent. This establishes equivalence between all three

methods for probing chaos in the chosen gravity background. Explicit non-trivial dependencies of OTOC on the arbitrary critical exponent has also been studied. We further derive the eikonal phase approximation and Lyapunov exponent at the turning point of the null geodesic of the background geometry using the classical approach. Eventually we uncover different scattering scenarios in the near-horizon and near-boundary regimes.
